Proverbs Up-to-date No. 3

WHAT CAN'T BE CURED MUST BE ENDURED

Surely such passive suffering is no longer necessary, as *prevention* is the key-note of all medical thought in regard to *incurable* diseases. Diseases of the teeth cannot be cured, but the means for their prevention are known to, and practised by, professional men.

Cure is the voice of the past—*Prevention* the divine whisper of the present.

And it is in this vital matter of prevention that Gibbs Dentifrice is allied to the work of the Dentist. The formula for Gibbs Dentifrice is one that is heartily endorsed by leading Medical Authority; because it provides just those qualities demanded.

Gibbs Dentifrice has a saponaceous base and mild alkaline reaction. It produces a fragrant antiseptic foam that penetrates to every interstice and crevice of the teeth and mouth — removing all decay-causing deposits. The polishing agent is of just the correct texture to clean and polish without risk of abrasion. Moreover, Gibbs Dentifrice is very pleasant and economical in use. By giving powerful publicity to Gibbs Dentifrice in the National Press, Gibbs help the Doctor and Dentist to extend the scope of preventive dentistry.

GIBBS DENTURE TABLET

Gibbs new Denture Tablet is for cleaning Dental Plates (both gold and vulcanite), Bridgework and artificial teeth. It gives a high polish, removes stains, makes plate or teeth sterile and antiseptic without in any way injuring the softest gold or the finest vulcanite or platinum. The formula has been submitted to and approved by important members of the Medical Profession.

Beefex

The SUPERIOR STIMULANT

We shall be pleased to send a sample bottle of this superior and valuable Beef concentrate to any Medical Man.

HIGH Medical Authority, after an independent test, reports that Beefex is a genuine Beef Extract of high quality and purity and is superior to others. It is invaluable in cases of weakness, exhaustion, or malnutrition, and appeals to invalids of all ages by reason of its delicate flavour.

BEEFEX LIMITED, BEEFEX HOUSE, LONDON, E.C.1.

TO COUNTER ACIDOSIS

As SALVITAE contains 89% of Potassii et Sodii Citro-Tartras and 10% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease, through eliminating deleterious nitrogenous products and favourably influencing circulation, glandular secretions, peristalsis, and metabolism.

The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates, thus enabling the blood to keep the uric acid compounds in solution, and facilitate their removal.

Hexyl-Resorcinol (BOOTS)

Tested by the usual Rideal-Walker method, HEXYL-RESORCINOL (BOOTS) is shown to possess extraordinary bactericidal potency numerically very many times greater than that of the ordinary organic disinfectants in general use. At the same time, the prescribed dose has no toxic action towards man or animals.

HEXYL-RESORCINOL (BOOTS) is supplied in Enteric-coated Tablets—in bottles of 25 and 100 tablets. Special Gelatin Capsules—in boxes of 24 and 100 capsules—are also available.

Why the profession approves Mistol

FOR a number of years leading rhino-laryngologists have been recommending an oily spray solution containing menthol, camphor, eucalyptol and chlorbutol, for common cold, chronic rhinitis, hay fever, minor sore throats and lesser inflammations of the upper respiratory passages.

The makers of Nujol developed this suggestion so as to produce, after much scientific investigation, a product containing these ingredients in the form best suited for intranasal medication. Mistol was the result.

Administered with the dropper contained in each package, Mistol immediately spreads evenly over the nasal mucosa so as to form a thin protective film. It has the further property of clinging tenaciously, so as not to be dislodged by secretions. Further advantages of Mistol are that it may be taken as a gargle or nebulized into a fine vapour for inhalation.

Because its use is based on sound medical practice, Mistol enjoys the highest measure of professional approval and confidence.

Mellin's Food
A MILK MODIFIER

MELLIN'S FOOD is specially prepared for modifying and adjusting cow's milk to meet the nutritive needs of infants deprived of human milk.

No matter whether certified, pasteurised, dried, or condensed milk is employed, its digestibility and its value as nourishment for the baby is enhanced by the addition of Mellin's Food. In other words, milk in any form is better borne, more completely utilised, and its nutritive constituents more appropriately balanced if properly modified with Mellin's Food.

There is no milk modifier exactly like Mellin's Food, and its continued recommendation by a large number of members of the Medical Profession is ample evidence of its outstanding advantages.

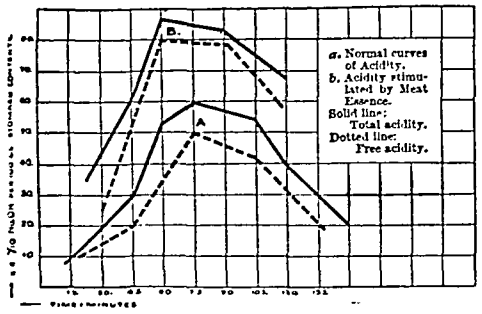
Further particulars and samples will be supplied on request.

MELLIN'S FOOD LTD., LONDON, S.E.15

"MODIFIED MILK IN INFANT FEEDING."

The above-named booklet of 64 pages will be gladly sent to members of the Medical Profession.

Conserves the patient's energy— no strain on the digestive system when these essences are taken



Graph showing acidity found when meat essences are taken

BRAND'S

ESSENCES OF BEEF

OR CHICKEN

When the appetite needs stimulus, and the body needs to be invigorated without demands on the digestive system, Brand's Essences of Beef or Chicken have been found to be indispensable. Recent scientific tests have shown that these essences are assimilated by the digestive organs *forty minutes quicker* than ordinary foods and without the formation of any residue.

In convalescence and in all cases of intestinal disturbances, whether the lesion is catarrh or cancer; in states of exhaustion when the patient's recovery is hampered by anorexia; in specific fevers and in all disorders associated with pyrexia; in the *post-influenzal* state and before and after operations, these Essences supply energy and prepare the system to accept and digest a more solid diet.

Hygienically prepared by an *exclusive* process from the finest freshly-killed English meats, Brand's Essences of Beef or Chicken are suave and non-irritant in action. For these reasons 99 doctors out of every 100 recently interviewed, recommend them. Samples will be gladly sent on receipt of a professional card. Brand & Co. Ltd., Dept. F.26, Mayfair Works, South Lambeth Road, London, S.W.8.

5% of pure iron (Fe) in readily assimilable form

. . . does not constipate, disturb digestion or discolour teeth

Colloidal Iron Concentrate	83%
Pure Alcohol	6%
Sugar	10%
Flavouring	1%

That is the formula of this tonic preparation, which contains a larger percentage of assimilable iron than has hitherto been provided in either a general or colloidal form. A more rapid response may therefore be anticipated from the administration of this preparation, which is very pleasant to take and well tolerated by all patients.
Idozan has no constipating effect, it does not derange the stomach or discolour the teeth. Though incompatible with alkaline salts, it may be combined with Liq. Arsenicalis and vegetable tinctures. It is therefore very suitable for therapeutic administration, where it is desired to give large doses of iron; both as a restorative after illness and in cases of anæmia it can be prescribed either with or without additional drugs with confidence and freedom.

The Treatment of Whooping-Cough

The laevorotatory alkaloid of the plant Ephedra Vulgaris.....a useful coadjuvant treatment of whooping-cough, especially when it is complicated with asthmatic bronchitis or bronchiectasia or asthma.
—(J.A.M.A., 22.11.30, p. 1626.)

Ephedrine B.D.H. is the natural laevorotatory alkaloid —it is prepared in the B.D.H. laboratories from the Chinese plant Ma Huang (Ephedra Vulgaris).

In the form of an elixir it is particularly palatable to children suffering from whooping-cough.

Ephedrine B.D.H. is issued also in Tablets, as an Inhalant, a Throat Spray and a Nasal Jelly.

To ensure that you are prescribing the natural laevorotatory alkaloid of Ephedrine always specify B.D.H.

IMPORTANCE of STARCHY FOODS in INFANT DIET

Tests by a great biochemical institute prove this wheat cereal invaluable as first solid food

LEADING practitioners to-day are agreed that it is vitally important to introduce a *starchy* food into the diet of infants at a very early stage.

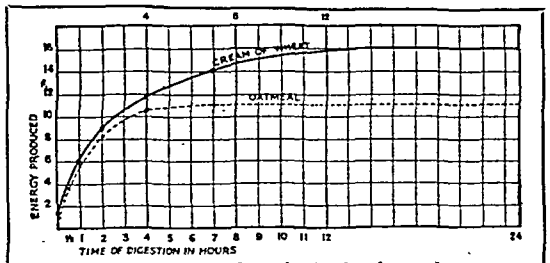
In a recent article on Starch Feeding (*The Practitioner*, July, 1930) a leading paediatrist stated:

> The addition of starch to an infant diet allows carbohydrate digestion to take place more slowly and there is less tendency for fermentative diarrhoea to occur.
>
> Instead of the blood stream being suddenly flooded with carbohydrate, and its absorption being extremely rapid, such starch must first undergo hydrolysis, and is then absorbed over a period lasting almost until the next feed.
>
> Starch is a useful addition to sugar to metabolize the fat in an infant's diet, and the presence of a colloidal solution of starch (cooked) retards curd formation, and therefore adds to the digestibility of milk.

This authority has placed "Cream of Wheat" on his diet sheets, as a first solid food for infants.

Greater digestibility—50% *higher sugar-yield.*

Long successful as an infant diet, this wheat cereal has recently been tested exhaustively by one of the leading



It will be seen that after 4 hours the digestion of oatmeal was practically at a standstill while that of "Cream of Wheat" continued at a scarcely diminished rate for a further 4 hours. When digestion was complete, the sugar from "Cream of Wheat" was nearly half as much again as that from oatmeal — making it productive of 1½ times as much energy.

biochemical institutes of Great Britain. Comparison of "Cream of Wheat" with oatmeal proved not only that the former is more digestible, but that in its absorption—a process continuing twice as long as that of oatmeal—it yields 1½ times as much sugar and thus of energy.

"Cream of Wheat" is an extremely palatable product made from the kernel of the finest hard wheat. It contains 72% starch, and is free from any harsh parts which might irritate the intestinal tract. It is therefore invaluable, not only as an infant's food, but for patients during the post-operative period and convalescence. If you would care to examine the product we shall be delighted to supply you gratis with a sample and a detailed account of the tests. Please enclose your professional card to Dept. W.1, Fassett & Johnson Ltd., 86, Clerkenwell Road, London, E.C.1.

EVANS' THROAT Pastilles

MADE BY

EVANS SONS LESCHER & WEBB Ltd.

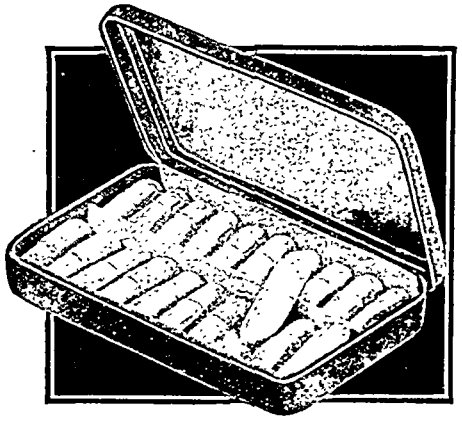
THROAT THERAPY.

Evans' Pastilles are prepared to a formula of the Liverpool Throat Hospital. Their action is soothing and demulcent, the formula being carefully balanced with both these objects in view. Evans' Pastilles relieve harshness and irritation and maintain their effect for some time after the pastille has dissolved.

Sold in 1/- tins or in bulk for dispensing.

A physician's sample will be gladly sent on request.

A *New* chemo-therapeutical preparation *for the treatment of influenza, septic diseases and toxemias*



Used in America for treating Influenza for the past two or three years with great success. The physician's sample illustrated here will be sent to you free on request.

Indications.
Influenza Colds, Pyelitis, Puerperal Sepsis, Surgical Sepsis, Bronchial Asthma, Obstetric Morbidity, Cystitis, etc.

DISULPHAMIN is a mixture of Sulpho-salicyl formol sodium nucleinate and Dimethylamino-antipyrin combined with camphor. The antitoxic action is based on the assumption that Disulphamin transforms the toxic colloid to a crystalloid, thereby facilitating its dialysis through the walls of the blood vessels, and accelerating its elimination by the kidneys.
While phenol is bactericidal in a 1/100 dilution, Disulphamin is bactericidal in a dilution of 1/10,000 to 1/50,000.
In a series of tests made in the treatment of Influenza with Disulphamin, it was found that the course of the disease was materially shortened, and very seldom did Broncho-pneumonia or other complications supervene. Although the etiology of influenza has not yet been clearly determined, it appears that Disulphamin exerts a polyvalent action.
The clinical results thus far obtained are so encouraging that physicians have ample justification for employing Disulphamin in Febrile Toxemias arising from Sepsis.
Samples and literature, including charts of actual tests and important hospital findings, will be sent free on request to Messrs. COATES & COOPER, 41, Great Tower Street, London, E.C.3.

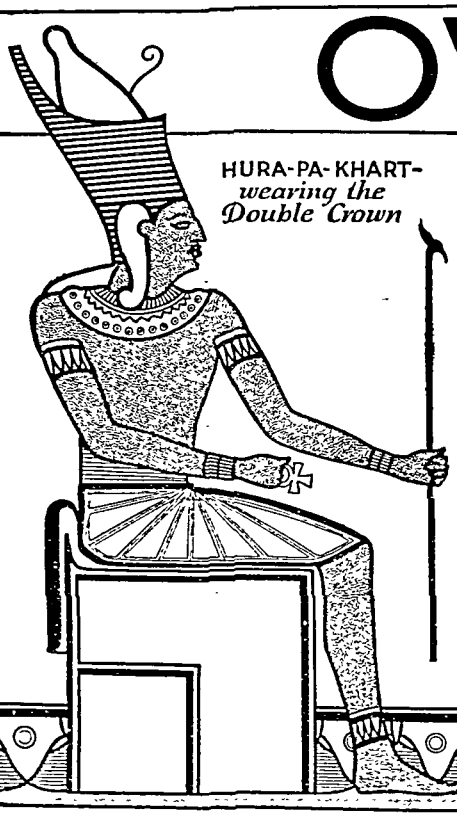
OVALTINE



HURA-PA-KHART-
wearing the Double Crown

FOR HEALTHY NUTRITION.

In every condition in which the need of a nutritious and easily digested food is indicated the advantages of "Ovaltine" are definite and many. In no case need the physician hesitate to order its liberal use.

"Ovaltine" is a highly concentrated extraction of malt, milk, and eggs. It is almost completely absorbed by the system, and because of its complete absorption, and because it is a form of nourishment complete in every respect, "Ovaltine" tones, strengthens, reinforces, and reinvigorates the whole body.

"Ovaltine" is purin-free. Its use neither aggravates the tendency to arterio-sclerosis nor favours the accumulation of uric acid in the system. This delicious food beverage sustains life ideally by promoting the healthy activity of the bodily functions.

A liberal supply for clinical trial sent free on request.

Works: KING'S LANGLEY, HERTS. M 247.

A New Standardised and Stable

Liquid Preparation of Ergot

It is now established that the characteristic physiological effects of the official ergot of rye are due to the alkaloid Ergotoxine, and that the comparative inactivity of the official liquid extract of ergot is accounted for by the fact that the ergotoxine content of this preparation is negligible.

An entirely new preparation—named Ergodex—which surpasses all official preparations of ergot in its usefulness is now available to physicians.

Ergodex is stable and highly active, it represents the whole alkaloidal content of the drug, and, therefore, its whole characteristic activity. It is miscible in all proportions with water without precipitation. It is physiologically standardised to contain 0.03% of ergotoxine, and will be found to exert the full therapeutic effect of genuine ergot.

Ergodex is administered orally, the usual dose being 10 minims to 30 minims. It is issued in amber-coloured bottles containing 60 c.c. (2 fl. ounces) at 4/6 per bottle.

Local Anæsthesia in Surgical Practice

TUMOUR OF BRAIN.

Typical Case.

L. B., male.

Diagnosis: Brain tumour in the left arm and leg centre.

Operation: Decompression. Ligation of varicosities.

Anaesthesia: 100 c.c. of a 1 per cent. Novocain-Adrenaline solution.

Operation: Ten minutes after making the infiltration a horseshoe-shaped flap was turned down on the right side over the vault of the cranium. The skull was opened by means of the Martell drill and a bone flap was turned down by the use of a motor saw and dura guard. This procedure was entirely painless to the patient, and he did not even complain of the grating of the saw. The patient made a prompt recovery.—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

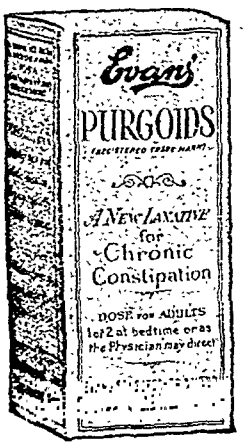
PURGOIDS

Purgoids are a most effective combination of Phenolphthalein, Aloin, Ipecac, Belladonna, etc., in sugar-coated tablet form. Of great value in cases of constipation, acting without depressing action. Peristalsis is promoted without griping and intestinal secretion is increased.



In long-standing cases of chronic constipation it has been noted that patients have fully recovered, not finding any further laxative necessary. They have been found to be of special value to nursing mothers, as they do not affect the baby.

Issued in bottles of
25, 100, 500, and 1,000.

A Physician's sample will be sent with pleasure, on request.

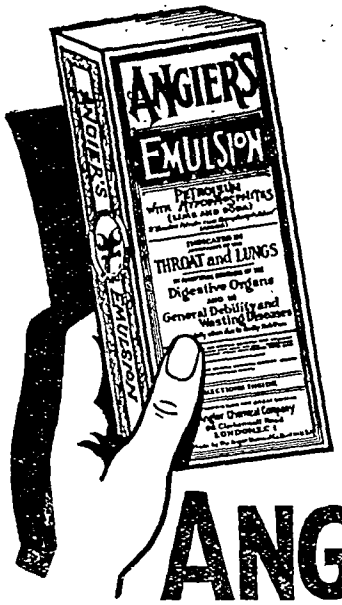
THE ORIGINAL AND STANDARD EMULSION OF PETROLEUM

In Gastro-Intestinal Disorders

of a catarrhal, ulcerative, or tubercular nature, Angier's Emulsion is particularly useful. The minutely divided globules of petroleum reach the intestines unchanged, and mingle freely with intestinal contents. Fermentation is inhibited, irritation and inflammation of the intestinal mucosa rapidly reduced, and elimination of toxic material greatly facilitated. An improved state of the digestive functions and modification of the various symptoms traceable to auto-intoxication are notable results.



During Convalescence

After fever, dysentery, operations, or after any serious illness, Angier's Emulsion will improve and strengthen the organs of digestion and assimilation and enable patients to derive the fullest benefit from any prescribed diet. The creation of appetite and the return of normal digestion is quickly brought about by its regular use.

Frail, Nervous Patients.

respond actively to Angier's Emulsion. It is a tonic in effect and an aid to digestion. Being a perfect Emulsion, it is presented in a form pleasing to the taste and acceptable to the most fastidious. Its good effects are accomplished in a safe and natural manner without entailing any extra work upon the weak or overburdened system.

Alternative Methods in the

TREATMENT OF BOILS CARBUNCLES & FURUNCULOSIS

Antivirus

The latest method, which has proved so useful with patients who object to injections, consists of local treatment with Staphylococcus Antivirus. Reports from hospitals and Skin Specialists state that this Antivirus is as efficient or more efficient than subcutaneous inoculations with Vaccine.

Detoxicated Vaccine

Practitioners who prefer the more orthodox forms of treatment are recommended to use Detoxicated Staphylococcal Vaccine; its special feature is the production of great immunity with little or no reaction. This is achieved by removing all the toxic elements of the germ during the preparation of the Vaccine. Doses up to 50,000 millions are given without malaise.

Ordinary Vaccine

To meet the requirements of those who consider that a slight reaction has definite therapeutic value Ordinary Staphylococcal Vaccine is available. It has proved generally successful and is very inexpensive.

SCULPTURED DOOR INFLUENCED BY COPTIC ART AND INSPIRED BY ARAB LOVE OF THE FANTASTIC.—This masterpiece of chiselled wood is an unmistakable example of Islamic art. The beautiful written characters of the Arabic language are combined with fine effect in the decoration. At the centre is an eight-petalled flower, around which eight stems are interwoven to form a polygon with eight points; these being produced give rise to eight flowing arabesques, and the whole design is enclosed within a motif, which also carries the ornamentation to the limits of the panel. The corners are decorated with similar arabesques contained within triangular outlines having projections which reach forward towards the central medallion. An inscription which forms an integral part of the design has a unifying stem running through it.

NIGHT OR MORNING?

WHEN TO TAKE LAXATIVES

There can, of course, be no universal rule as to the taking of laxatives. Circumstances vary, and only the physician is in a position to judge their relevance. But experience seems to show that a good deal of harm is often done by the common habit, continued over long periods, of taking aperients at bed-time. At night, the colon is normally much less active than in the day; and it seems unwise, unless special reasons exist, to stir it to unwonted activity during the hours which should be allotted to sleep. It is probable that much insomnia and many rest-disturbing dreams have their origin in the taking of a nightly purgative.

When there is an habitual tendency even to slight constipation, not fully remedied by diet and exercise, it is suggested that the most satisfactory result can generally be obtained by the taking, first thing in the morning, on an empty stomach, of a simple refreshing saline draught, such as Eno's "Fruit Salt" provides. Eno is a saline effervescent of fine granular consistency, containing no trace of irritating mineral salts, such as Epsom and Glauber. Owing to its purity and texture, it is agreeable to the palate; its pleasantness owing nothing to added sugar or flavouring matter, from both of which it is entirely free.

"Urgent Abdominal Diagnostics."

The Proprietors of ENO'S "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest of their series of "Medical Reminders"—with or without a bottle of their preparation as desired. "Urgent Abdominal Diagnostics" summarises the salient facts which need to be ever at the front of the mind when faced with an abdominal emergency. The diseased conditions dealt with include those which most often call for immediate surgical attention. It is bound in black morocco limp to conform to the style of the previous publications in this series.

Observations ON THE MEDICINAL TREATMENT OF CHRONIC ARTHRITIS

(With Key Index)

BY

N. MUTCH, M.D., F.R.C.P.

PHYSICIAN TO GUY'S HOSPITAL

There clearly is great pleasure in variety. Drugs and potions have been furnished in profusion to combat this disease. Some are frankly quack, others vague traditions such as black snake root, poison ivy, maté, celery oil, and manaca. Others, again, are simple mixtures of well-known substances glorified by a registered name—for example, colchicum and colocynth in "Bejean's specific" and "Laville's liqueur." Apart from these, however, there are more than a hundred substances and preparations of published composition whose use is sanctioned by laboratory experiment or common prescription. A pretentious nomenclature suggests great diversity in their modes of action, but chemically they fall into a conveniently limited number of groups. It is part of the purpose of this communication to provide a guide to the formidable array, and enable the reader to see at a glance what result to expect from any particular preparation. Accepting the common view that the bulk of chronic rheumatic disorders are produced by toxin or bacterial seepage from one or more septic foci, it is possible to make a rapid survey of the therapeutic field. Lowered resistance, sensitization, perverted metabolism, and deranged endocrine secretion in many cases probably prepare the soil, but their discussion here would lead too far from the main thesis of this paper. Apart from these considerations the treatment falls under the following headings.

A. Focus Treatment

The teeth, throat, sinuses, and genito-urinary passages need surgical care and an intelligent use of antiseptics. The danger to be avoided is the infliction of chemical trauma. The stomach and intestines require careful survey that a scheme of treatment can be organized to reduce putrefaction and the harbouring of saprophytes with infective powers which enable them to penetrate[22 23] the living tissues of the bowel wall. The chief methods are:

1. Elimination of food stasis.

2. Simplification of the diet and correction of faults in feeding and secretion with the object of reducing the amount of undigested putrescible material in the colon. A correct meal routine, efficient mastication, hydrochloric acid if needed, takadiastase, and the more potent preparations of pancreatin are important means to this end.

3. Limitation of bacterial action by antiseptics such as ichthyol salicylate, salol, or guaiacol carbonate. The last-mentioned is not antiseptic itself, but slowly liberates free guaiacol throughout the entire length of the bowel, and so exerts a mild antiseptic action at all levels. The effects of antiseptic treatment are not striking, and even the most modern products of research do not seem to achieve very much in this direction.

4. Toxin fixation by the use of an insoluble adsorbent kaolin[24] or charcoal capable of removing from solution toxins thrown off by bacteria and toxic proteoses produced from proteins by bacteria or perverted digestion in the gut. It is rarely possible to give sufficient charcoal to secure complete protection from these substances, but kaolin is easily taken in amounts commensurate with the mass of faecal matter to be dealt with. Most kaolin contains harmful microscopic particles of quartz and mica. For continued use it is important to employ one of the well-known proprietary brands of colloidal kaolin which have been specially freed from such deleterious matter.

B. Local Treatment

Apart from orthopaedic methods most local treatment resolves itself into attempts to improve the circulation in the affected parts. Radiant heat, steam, hot wax and mud, and diathermy are invaluable when correctly applied. Medicinally there is a galaxy of counter-irritants, some elegant, some brutal—alcoolat de Fioraventi, oil of amber, saffrol, Chillie paste, a host of others, and the common embrocations of the *Pharmacopoeia*. The group which stands out most clearly is that of oil of wintergreen, and here the registered trade nomenclature calls for a little analysis. The advantages of wintergreen are that, in addition to its causing vasodilatation of the skin and underlying parts, it has a mild local anaesthetic action on the skin, and is absorbed, producing a general salicylate effect in mild degree.

Methyl Salicylate Group

(Syn. Oil of Wintergreen, Gaultheria Oil, Betul Oil)

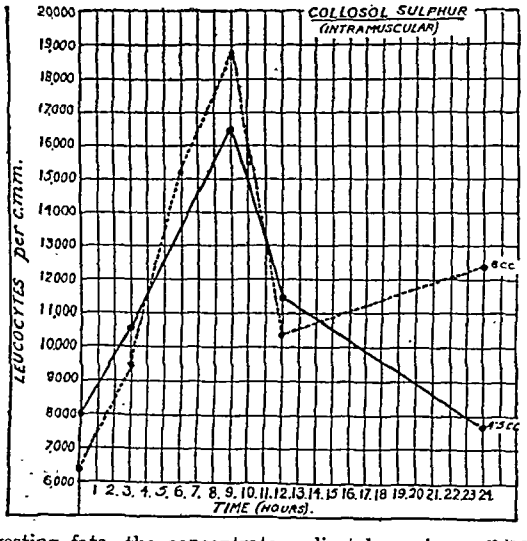
Applied externally

$C_6H_4.OH.COOCH_3$

Amysal	=	Amyl salicylate
Bengue's balsam	=	Methyl salicylate and menthol
Betul-ol	=	Methyl salicylate, menthol, and chloral
Ethyl salicylate		
Glycosal	=	Glyceryl monosalicylate
Mesotan	=	Methoxymethylsalicylate
Methyl aspriodine	=	Methyl acetyl iodosalicylate
Rhesal	=	Glyceryl monosalicylate
Salen	=	Ethyl and methyl glycolylsalicylate
Saliceral	=	Glyceryl monosalicylate
Salit	=	Borneol salicylate
Spirosal	=	Ethyleneglycol monosalicylate

C. General Resistance

1. Healthy surroundings, ultra-violet light, and a richly vitaminous diet are invaluable. Vitamins A and D are particularly important, and are easily given as cod-liver oil. For obese subjects, and those who have difficulty in digesting fats, the concentrate radiostoleum is available, and with it calcium preparations, the gluconate[16] or lactate, can be profitably combined.



2. Non-specific reactive therapy. A number of useful schemes have been devised:

(i) The facilitation of antibody formation by the injection of manganese.

(ii) Artificial leucocytosis by subcutaneous or intramuscular injection of suitable reagents, such as sodium nucleinate or colloidal sulphur either in a watery or an oily medium, and many other substances. The graph illustrates the effects of intramuscular collosol sulphur on the leucocyte count. The

latter was kindly worked out for me by Dr. R. S. Bruce-Pearson.

(iii) Intravenous injections where more opportunity is given for colloid interaction—for example, cibalbumin and certain bacterial emulsions such as T.A.B. Here again leucocytosis plays a part, but is certainly not the only agency at work. The method is not free from risk, and dosage is difficult to assess in terms of expected reaction in the rheumatic parts.

Other substances—for example, milk, peptone, and yatren-casein—probably act in analogous fashion, but should not be given intravenously.

D. Specific Resistance

Inoculation with vaccines made from the infective bacteria of the various foci provokes pain reactions in the rheumatic areas, leads to antibody production, and is undoubtedly, on occasion, followed by definite clinical improvement. Up to the present time it has proved impossible to devise a reliable method of determining which strains should be incorporated in the vaccine. Until our knowledge is greater it is advisable to include all infective strains isolated.[25]

E. Vicious Circles

Results which react on causes and aggravate the original mischief are to be found in most diseases of long standing. The rheumatic group is no exception. Here subthyroidism and anaemia are the chief offenders.

(i) Subthyroidism may antedate the lesions in the joints or be collateral with them, and probably represents the effect of the focal toxins on the thyroid gland. When once established it impairs metabolism and the defence mechanism, so permitting the morbid process at foci and joints to proceed more briskly. All degrees of subthyroidism are met with, varying from the most benign to fully fledged myxoedema. Their correction by suitable doses of the dried gland has a remarkably beneficial effect on the whole syndrome.

(ii) Anaemia of the ordinary secondary type is almost universal in the more progressive forms of chronic arthritis, and may assume serious proportions; 80 per cent. haemoglobin is a common reading, but figures as low as 30 per cent. are not unknown. There is no evidence of active haemolysis, and the poverty of the blood is probably due to toxic depression of the bone marrow. It is very prejudicial, and should be corrected by iron therapy. Natural ferrous iron waters are useful, but for routine use a scale preparation or iron phosphate is effective if the bowels are acting well, and one of the strong colloidal preparations—for example, idozan—if there is any tendency to constipation.

The therapeutic field has now been represented in perspective from the viewpoint of accepted pathology, and we are in a position to deal critically with the vast array of drugs advertised for use in these conditions. They will be classified chemically, and each group assigned its appropriate place in the general scheme of treatment.

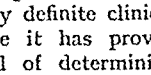
Aspirin

The 1,000 tons of aspirin sold in this country annually are remarkable testimony to the utility of the drug. Its outstanding effects are relief of rheumatic pains and diminution of stiffness in so far as this is not due to ankylosis or adhesions. The ultimate course of the disease does not appear to be influenced directly, but indirectly; something must be gained by enabling the patient to sleep and affording him a respite from the exhausting monotony of his pain. A portion is lost by decomposition in the stomach. The rest is disseminated very widely, and salicylates can be recovered from the joint tissues themselves, also from pathological and normal synovial fluid. Its power of relieving pain in chronic rheumatism seems almost to be specific, and is far greater than that of sodium salicylate. It is, however, exercised in a limited way in other conditions. The secret of its action is well concealed, and may involve changes in tissue tension with release of compressed vessels or nerves.

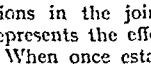
A number of observations point in this direction. Both Oswald[26] and Hanzlik[10] have shown that aspirin alters the permeability of certain colloid membranes. It also causes retention of fluids in the body, with a diminished urinary flow and a rise in body weight. The excess is not accommodated in the vascular system, because there is no change in the concentration of haemoglobin. It must therefore be in the cells themselves, the tissue spaces, or lymphatics.[12] Finally, idiosyncrasy to aspirin often shows itself as urticaria or generalized oedema, so that it would appear reasonable to assume that some kindred peripheral action around the joints is responsible for the loss of pain rather than to invoke a central narcotic action on pain perception in the brain.

Aspirin Group

(Syn. Acetyl Salicylic Acid)



Aspro Empirin Genasprin	}	A few registered names of brands of aspirin
Aspiphenin	=	Aspirin and phenacetin
Diaspirin	=	Succinyl salicylic acid
Metaspirine	=	Aspirin and caffeine
Nopirine	=	Aspirin, phenacetin, and caffeine
Rhofeine	=	Aspirin and caffeine
Aspriodine	=	Iodoaspirin
Novaspirin	=	Methylene citryl salicylic acid
Salacetol	=	Acetyl methyl salicylate
Sedaspirin	=	Bromo aspirin



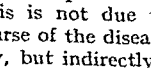
Sodium cresotinate (resembles aspirin in relieving the pain of chronic rheumatism)

Antipyrin

The arthritic patient's demand for relief from pain has led to the development of a series of simple analgesic drugs with an admittedly central action. If derivatives of codeine and morphine are excluded most of the others will be found to be modifications of antipyrin. In this class there is great scope for mystification, because the same substance can be described in widely different chemical terms. For example, pyramidon (amidopyrin) may be referred to as dimethylaminoantipyrin or as dimethylamino-phenyl-dimethyl-isopyrazolone. Both names are correct, and although to most medical men not engaged in pharmacological or chemical research they are mere mumbo-jumbo, they carry a scientific cachet which appeals to many and which can be exploited by the vendor of drugs. The close relationship between most of the members of the series will be seen at a glance in the table appended. In addition to these a pharmacologically analogous drug phenocoll hydrochloride, a derivative of phenacetin, has been much used.

Antipyrin Group

(Syn. Phenazone, Dimethyloxyquinizine, 1-phenyl-2:3-dimethyl-5-pyrazolone)



Acetopyrine	=	*Antipyrin*acetosalicylate
Compral	=	Dimethylamino*antipyrin* (that is, pyramidon) + a modified urethane hypnotic
Gardan	=	Dimethylamino*antipyrin* (that is, pyramidon) + methylamido-methane sulphonate of *antipyrin* (that is, *novalgin*)
Melubrin	=	Amidomethane sulphonate of *antipyrin*
Novalgin	=	Methylamidomethane sulphonate of *antipyrin*
Pyramidon	=	Dimethylamino*antipyrin*
Pyrethane	=	A combination of *antipyrin* and urethane
Salipyrin	=	*Antipyrin* salicylate

SULPHUR

It is a little difficult to see why sulphur should be so useful in modifying the course of chronic rheumatic diseases. Its use undoubtedly has received wide sanction over a long period of years. Most of it passes unchanged through the bowel and is excreted unchanged in the faeces, so that it has ample opportunity to affect the contents of the entire digestive tract. Although inert in inorganic association it readily reacts with proteins in an alkaline medium, giving rise to sulphides, which are bactericidal, irritant, and laxative, sulphuretted hydrogen, and organic sulphur compounds. All of these can be recovered from the stools.[13] Sulphur is far more than an intestinal antiseptic. It is a detoxicating agent in virtue of its power of interacting with otherwise putrescible residues in the colon. It is a kind of scavenger modifying and destroying these protein remnants just as it destroys necrotic material and slough when packed into a contaminated wound. Varying amounts pass into the circulation, possibly as sulphides. As much as 50 per cent. of milk of sulphur may be dealt with in this manner. Up to the present, however, no systemic effects have been observed. There is no formation of sulphaemoglobin and no other evidence of free sulphide in the blood. Sulphides are active reagents and poisonous. Even small amounts would be expected to irritate the cortex or medulla. Sulphides appear in the urine, but most of the absorbed sulphur is eventually excreted fully oxidized as sulphate.

As explained before, the injection of colloidal sulphur is another matter. The fever and leucocytosis provoked in this way can be regarded as the outcome of a non-specific interaction between the colloid particles injected and those of the body fluids.

Sulphur Group

Azufrol Collosol sulphur	}	Colloidal sulphur (proprietary)
Dutch drops	=	A preparation of sulphur, linseed oil, and turpentine
Oscol sulphur Sulfoiodol Sulfurion Thionhydrol Vulcase	}	Proprietary forms of colloidal sulphur

IODINE

The clinical value of iodine preparations is undoubted but limited in its scope. In the amounts prescribed its theoretical antiseptic value in gut and tissues must be negligible. One of its most pronounced features is that of storage. After a single half-gram dose of iodide, the element can be detected in the urine for forty hours, and after a short course it may take three weeks to clear the urine again.[14] There are two obvious ways in which it may help the rheumatic patient. In the first place it may act indirectly by stimulating a defective thyroid gland and normalizing its secretion chemically as well as in amount. Iodine storage occurs in the thyroid gland to a greater extent than in any other tissue. The administration of iodine produces histological changes in the gland,[15] raises the basal metabolic rate, and increases the functional activity of the thyroid substance as estimated by its effect on the growth of tadpoles.[19]

Another opportunity is afforded by the local accumulation of iodine near inflammatory foci. Not only does special concentration occur in syphilitic gummata, but also in the lipoids of tuberculous areas,[4] and in pus and other inflammatory exudates[17] where it is found as inorganic iodide. Suitable conditions are thus provided, not only for assistance through the thyroid, but for a direct action in the joints and inflammatory foci themselves, whilst the storage and slow excretion ensure steady uniform action the whole day through.

The favourite old French tincture, various colloidal forms such as iodor and collosol iodine, and the pharmacopoeial preparations of iodides and of the element itself are all in common use. There are, in addition, large numbers of iodine compounds on the market testifying to the popularity of the drug. About them, Erlenmeyer and Stein[5] have made the sweeping generalization that all remain inert until decomposed in the tissues or the gut with the liberation of simple iodides, which are taken up again by the body colloids. They fall into two groups: those in which the iodine is combined with proteins and those in which it is linked with fats, fatty acids, and kindred substances. The former are digested in the bowel and the iodine absorbed as simple iodides, so that nothing much is gained beyond delayed absorption. The latter gain the lymphatics unchanged, and undergo preliminary distribution in a manner peculiar to themselves, attaching themselves to the body lipoids.[1 6 20]

The lists below are by no means complete, and iodine occurs in several other combinations, as in yatren, iodaseptine, iodoxybenzoic, etc., considered in other connexions.

Iodine
(Protein Group)

Iodalbacid	
Iodalbin	With serum albumin
Iodalose	With peptone
Iodethylglycin	
Iodocasein	
Iodogelatin	
Iodoglidine	With wheat gluten
Iodone	With peptone
Iodoprotein	With albumin
Iodotannate	
Iodurase	Iodides and yeast albumin
Iolase	Iodine with yeast albumin
Seroden	With serum protein

Iodine
(Fatty Group)

Calioben	=	Calcium iodobehenate
Iodatol	=	Iodized vegetable oil
Iodicin	=	Calcium iodoricinoleate
Iodinol	=	Iodized sesame oil
Iodipin	=	Iodized sesame oil
Iodostarin	=	Diiodotaririnic acid
Lipiodol	=	Iodized vegetable oil
Lipoiodine	=	Ethyl diiodobrassidinate
Oliolase	=	Iodized vegetable oil
Sajodin	=	Calcium iodobehenate

RADIO-ACTIVE SUBSTANCES

Radium chloride can be safely given by mouth in dose of 1/100,000 milligram several times a day for a number of weeks at a time. It is absorbed rapidly, permeates the tissues freely, and, after special storage in the liver and spleen, is eliminated through the bowel wall.[3 27] During its stay in the body some breaks up into its degradation products known as emanation, niton, or radon, and into α rays. Radon can be detected in the air, exhaled through the lungs, and in its turn emits β and γ rays, the latter being electro-magnetic waves of decidedly shorter length than those employed in deep x-ray therapy. The γ rays are probably the factor most closely concerned in the pharmacological action of radium when taken in small doses by mouth.

The most definite effects are diuresis, lowering of the blood pressure in certain common varieties of hyperpiesia, and the provocation of local reaction around inflammatory foci. In chronic arthritis this usually takes the form of an increase of pain and swelling. With the dosage mentioned the reaction is not usually noticeable until the radium has been taken for several days. At the completion of a short course it subsides and is usually followed by a beneficial swing of the clinical pendulum in the opposite direction. A similar result can be achieved by the administration of a solution of radon or emanation in

water, but the effect is less steady and more transient, partly because of rapid elimination of radon through the lungs, and partly because radon has a very short life, being fairly completely dissipated in a few days' time.

Agents conveniently at our disposal and arranged in increasing order of potency are as follows:

Spa waters containing radon.
Water which has been allowed to stand in a container in which radium ore is incorporated. This also relies on its radon content.
Solutions of radon produced under controlled laboratory conditions from pure radium salts, as at the Radium Institute.
Scleradium, stated to contain a standardized amount of radium chloride itself in a fairly large saline tablet.

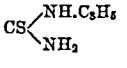
Other radio-active substances also are available. Thorium, used extensively in the manufacture of incandescent gas mantles, undergoes slow and continuous molecular degradation, giving rise to mesothorium, which gives off γ rays whilst further degradation is taking place. Mesothorium is isolated as a by-product in the manufacture of gas mantles, and the yearly output was at one time estimated as equivalent to about 1/2 gram of radium in terms of γ radiation, but its average life is only a few years in contrast to the 2,600 years of radium. Mesothorium is supplied in solutions of various strengths up to 2 micrograms of the bromide per c.cm.

It is important to remember that solutions of radon must be fresh, because they become inactive in less than a week. Mesothorium keeps for several years, and radium indefinitely.

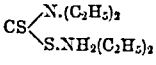
THIOSINAMINE

This substance was introduced by Hebra and Unna in 1892. It does not dissolve at all freely in water. Simple soluble modifications such as sodio salicylate (fibrolysin) are therefore used instead. It provokes a widespread reaction with metabolic effects, evidenced by fatty degeneration of parenchymatous organs and increased elimination of nitrogen. Clinically the reaction produces malaise and pyrexia, and appears in some cases to be followed by the resolution of low-grade indolent localized infections, with a diminution in the fibrous and other chronic inflammatory tissues which surround them. A list of preparations is given below. In this connexion contramine should be mentioned. Its chemical relationship to this group will be seen by comparing its published structural formula with that of thiosinamine.

Thiosinamine



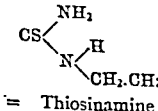
Contramine



It is also a reactive drug, and is supposed to produce its effect by physical interaction with the body colloids rather than by simple chemical means. Our knowledge of the mode of action of these admittedly potent drugs is still extremely scanty, and it would appear rash to use them unless the patient can be kept under close medical observation.

Thiosinamine Group

(Syn. Allyl Sulphocarbamide, Allyl thio urea)

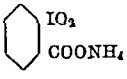


Cicatricine	=	Thiosinamine and antipyrin
Fibrolysin	=	Thiosinamine sodio salicylate
Iodolysin	=	Iodine derivative of thiosinamine
Rhodallin	=	Thiosinamine
Tiodine	=	Thiosinamine ethyl iodide

IODOXYBENZOIC ACID

This substance and the related compounds iodosobenzoic and iodobenzoic acids have been known to pharmacologists for many years, but the group was not introduced into clinical medicine until 1926, when Young and Youmans published a series of cases treated with ortho-iodoxybenzoates. Given by mouth iodoxybenzoates cause sweating and a certain amount of epigastric discomfort, followed by relief of joint pain. It is more usual to administer it intravenously as a solution of its sodium or ammonium salt, the latter being preferable because of the decided tendency of the sodium salt to cause local thrombosis. It is bactericidal to staphylococci and streptococci, even in the presence of serum,[2] but it seems unlikely that this property is responsible for the clinical effects following intravenous injection. Used in this way it provokes a polymorphonuclear leucocytosis, and in experimental animals there is an increase in the formation of antibodies.[13] The immediate clinical effect is a smart reaction, with sweating, fever, nausea, and abdominal pain. Relief of joint pain and associated muscle spasm commonly follows, but is not usually very lasting. The unpleasantness of the reaction is a serious drawback to the use of the drug. Like thiosinamine, its effects are somewhat akin to those of non-specific reactive therapy.

Arthritin = Ammonium ortho-iodoxybenzoate



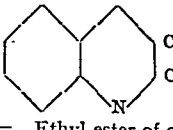
CINCHOPHEN

Nicolaier and Dohrn introduced this substance in 1908. Its popularity probably depends entirely on its pain-relieving qualities, which in acute rheumatic fever rival those of the salicylates themselves. Although aspirin is the most useful analgesic in chronic arthritis the antipyrin and cinchophen groups are keen competitors.

Scientific attention has been keenly focused on the increased excretion of uric acid which follows the use of this substance. The percentage of uric acid in the blood falls at the same time,[7 21] and suggests that cinchophen increases the permeability of the kidney to urates and so facilitates their excretion. The power of cinchophen to relieve pain is not confined, however, to those chronic arthritics with high blood uric acid values, and is, on the whole, more conspicuous in chronic infective arthritis than in true gout. Clinically there is little justification for its use if pain can be controlled in other ways. It does not seem to have any direct effect on the final result, and on quite a number of occasions jaundice, with serious degenerative changes in the liver, has followed the use of cinchophen and its derivatives. It is only fair to add that there is no evidence that the liver is attacked in every case; indeed, Graham (1926) showed that, even after long courses of the drug, liver function as measured by the levulose curve was usually unaffected. Nevertheless the incidence of acute liver changes in this connexion is too significant to pass unnoticed.

Cinchophen Group

(Syn. Phenoquin, Phenyl Cinchoninic Acid, Phenylquinoline-carboxylic Acid)



Acitrin	=	Ethyl ester of cinchophen
Agotan	=	Cinchophen
Atophan	=	Cinchophen
Atophanyl	=	Sodium cinchophen and sodium salicylate
Atoquinol	=	Allylcinchophen
Hexophan	=	Oxycinchophen
Losan	=	Sodium bicarbonate and cinchophen
Neocinchophen	=	Ethyl ester of methylcinchophen
Novatophan	=	Ethyl ester of methylcinchophen
Quinophan	=	Cinchophen
Tolysin	=	Ethyl ester of methylcinchophen

HEXAMINE

This drug is not often prescribed alone in chronic rheumatic conditions, but being an ingredient in a number of popular proprietary mixtures, such as urodonal, it must claim some attention here. When used in chronic arthritis the usual intention is to exploit its solvent action on uric acid, not to employ it as an antiseptic for the urine. The consideration is of theoretical interest only, and it is impossible to detect any fall in the uric acid content of the blood or any rise in the daily excretion even when full dosage is employed. Its clinical influence on the symptoms or the course of the disease is not apparent. It might conceivably produce a beneficial effect by liberating traces of formalin at the infected joint areas and primary foci. The concentration of formalin liberated from hexamine is determined by the acidity of the surrounding medium, and is not quite zero even at the point of neutrality to litmus. It can be shown that at a reaction corresponding to that of blood about 1/2 per cent. is split up into formalin after a few hours, and at the reaction of asphyxial blood the figure reaches almost 1 per cent.[4 11 29] Local CO_2 tension and acidity are definitely higher around areas of inflammation than elsewhere, so that some support is given to the idea that free formalin is produced in these situations. Whatever formalin may be liberated in this way is bound at once by protein, and loses its antiseptic properties. Nevertheless through this means it might indirectly influence the course of the disease beneficially. The reaction by which formalin is liberated is a balanced one. The prompt removal of formalin by protein fixation should therefore lead to the continuous production of more and more formalin as long as any hexamine remains. It must be admitted, however, that large doses of hexamine can be injected intravenously without provoking any obvious disturbances such as those associated with colloid shock or following the introduction of thiosinamine or iodoxybenzoates, and that most of it can be recovered again from the urine.

Hexamine Group

(Syn. Urotropine, Formin, Formamine, Hexamethylenamine, Hexamethylene tetramine, Methenamine)

$N_4(CH_2)_6$

Cystamine Metramine	}	Two of many proprietary brands of hexamine
Amphotropin	=	Hexamine camphorate
Borovertin	=	Hexamine triborate
Cystazol	=	Hexamine sodio benzoate
Cystoformin	=	Modified hexamine
Cystopurin	=	Hexamine sodium acetate
Formalol	=	Hexamine anhydro methylene citrate
Helmitol	=	Hexamine anhydro methylene citrate
Hetralin	=	Hexamine resorcin
Iodaseptine	=	Iodobenzo methyl hexamine
Mirion	=	Iodohexamine
Uralysol	=	Hexamine (+ helmitol, lysidine, and thyminic acid)
Uraseptine	=	Hexamine (+ helmitol, piperazine, lithium, and sodium benzoate)
Urodonal	=	Hexamine (+ lysidine, sidonal, and sodium bicarbonate)
Urogenine	=	Hexamine (+ piperazine, lithium, and sodium benzoate)
Uro-hexoid	=	Hexamine (+ lithium benzoate)
Vesalvine B.	=	Hexamine benzoate
Vesalvine S.	=	Hexamine salicylate
Citarin	=	Sodium anhydro methylene citrate (liberates formalin easily, and can be mentioned here, although not actually a derivative of hexamine)

PIPERAZINE AND OTHER URIC ACID SOLVENTS

Piperazine,[9 12] when added to urine, increases its ability to dissolve uric acid. Lithium salts increase the solvent action of water for uric acid, but in the serum and urine the excess of sodium nullifies the effect completely. It is entirely improbable that under clinical conditions these substances affect the urates in the tissues or the blood in any way. Even if it can ever be proved that they are able to exert some such action it will still remain to be shown that the patient benefits from the change. Piperidine and thyminic acid belong to the same pharmacological group. The clinical effects, if any, of using this class of substance in the treatment of chronic arthritis are quite imperceptible.

Uric Acid Solvent Group

(Excluding Hexamine)

Benzo-piperaz	=	Piperazine benzoate
Calcusal	=	Piperidine para sulphamine benzoate
Glycero-piperaz	=	Piperazine glycerophosphate
Lycetol	=	Dimethylpiperazine tartrate
Lysidine	=	Ethyleneethenyldiamine (also in uralysol and urodonal)
Piperazine	=	Diethylenediamine (also in uraseptine and urogenine)
Piperidine		
Quinic acid	=	Hexahydro tetraoxy benzoic acid
Salicyl-piperaz	=	Piperazine salicylate
Sidonal	=	Piperazine quinate (also in urodonal)
Solurol	=	Thyminic acid (a nucleoprotein derivative also in uralysol)
Thyminic acid		
Urazine	=	Piperazinecitrosalicylate
Uricedin	=	Lithium succinate
Urosin	=	Lithium quinate

With few exceptions the relatively inert lithium salts have been omitted, and no special mention is made of saline aperients or mineral base preparations. The lists are admittedly far from complete, but most of the preparations which have obtained a vogue in recent years have been included.

With so many substances at his disposal the medical man, bewildered, may well pause before giving his patient any positive advice at all. A critical survey of every organ and system is essential, and in making a therapeutic plan it is useful not only to keep in mind the balanced scheme of treatment outlined in the earlier part of this paper, but to decide whether the chief effort should be centred on the joints themselves, the septic foci, the digestive tract, the endocrines, general resistance, non-specific reactive therapy, or an attempt made to raise specific resistance to particular bacteria by vaccines. Clinical observation usually indicates clearly where the greatest advantage is to be secured. Suitable medicinal agents can then be selected with confidence. Revision will be needed from time to time to make good an advantage or to pass from one gain to the next objective, and little by little, with care and patience, what seemed at first impossible will be achieved.

Much care has been taken to ensure the accuracy of the chemical statements made, and I am greatly indebted to Professor C. S. Gibson for acting as censor in this matter. I should nevertheless welcome communications from any manufacturers who consider that their products have been misrepresented from the chemical point of view, and from any practitioner who has had outstanding success in the treatment of chronic arthritis with any drug omitted from the discussion or schedules.

CLOSED DRAINAGE IN THE TREATMENT OF EMPYEMA

WITH A REPORT OF FORTY-TWO CASES IN INFANCY AND CHILDHOOD*

BY

J. D. McEACHERN, M.D.

CHIEF SURGEON, WINNIPEG CHILDREN'S HOSPITAL

Hippocrates taught that in cases of empyema the operation to drain away the purulent effusion should not be performed before the fifteenth day after the onset of the illness. He also advocated irrigation of the cavity. His teachings therefore foreshadowed two principles in the modern treatment of this disease.

PRINCIPLES OF MODERN TREATMENT

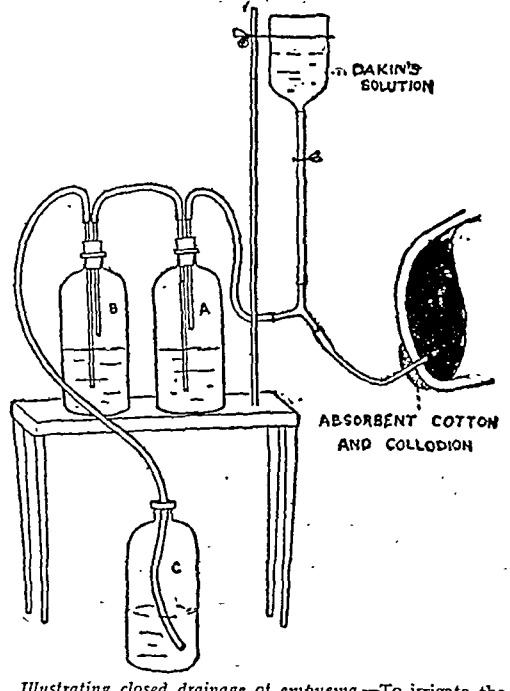
Delay before Operating.—Empyema is not to be regarded as a surgical emergency requiring operation as soon as it is diagnosed. The necessity of waiting until the adhesions between the lung and the chest wall are sufficiently firm to prevent the lung from pulling away from the chest when the thorax is opened is well recognized. It is also advisable in most cases to wait until the pneumonic process has subsided before continuous drainage of the empyema is undertaken, the pus being removed by repeated aspiration until such time as the pneumonia has resolved. All the cases here reported have been aspirated at least once—depending on the nature of the condition. In cases of empyema due to the streptococcus, effusions into the pleural cavity are prone to occur at an early date, and firm adhesions between the visceral and parietal pleurae do not take place as readily as when the infecting organism is the pneumococcus. Where the empyema is caused by the streptococcus, therefore, aspiration is persisted in longer than where it is due to the pneumococcus. In the latter case we feel that adhesions between the lung and the chest wall are sufficiently firm to prevent collapse of the lung after thick pus has been present for one week; while in the case of the streptococcus we consider that we must wait from two to three weeks for the above desired result. Here it may be well to point out that in aspirating pus from the pleural cavity, the utmost care should be taken to prevent air from entering the thorax. It is always very disappointing for a surgeon to find that an exploratory puncture has been performed, and that air has been allowed to enter the chest, with additional lung collapse and spread of infection.

Irrigation.—The second principle employed by Hippocrates was that of irrigation. While he washed out the cavity with wine and oil "to cleanse the surface of the lung," we use Dakin's solution to overcome the infection, to liquefy the masses of fibrin so that they will pass out though the catheter, and to soften the exudate which covers the surface of the lung and impedes its expansion.

Application of Negative Pressure.—The third principle—which Hippocrates did not employ—is the application of negative pressure to assist in expanding the lung and thus obliterate the cavity. Forty years ago Beulau inserted a catheter through a trocar into the thorax, drained off the fluid, and applied negative pressure drainage. Since that time the closed method of drainage in empyema has had some advocates and many adverse critics. Notwithstanding the advantages claimed by those who used the closed method, it has been slow in coming into general use. After a personal experience with the closed drainage combined with irrigation of the cavity with Dakin's solution in more than fifty cases of empyema, I have found that this way of treating the condition is so much better that I have abandoned the open method. I therefore take this opportunity of focusing attention on this subject, in the hope that those who have not hitherto given this method a trial will do so.

APPARATUS

I wish also to call attention to a very simple apparatus which I have employed for this form of treatment, as



Illustrating closed drainage of empyema.—To irrigate the cavity the rubber tube connecting the Y glass connexion with bottle A is clamped, after which the clamp is removed from the tube connecting the Y with the container for Dakin's solution; when the abscess cavity is filled the solution is clamped off and the clamp between the Y connexion and bottle A removed, allowing the solution to drain off by suction into bottle A. To remove the solution accumulated in bottle A, clamp both rubber tubes leading from the glass connexions in the cork; the cork may then be withdrawn and the bottle emptied without disturbing the siphon.

I feel that one reason why more surgeons have not given the method a thorough trial is the complicated nature of the apparatus described from time to time for its

* Read before a joint meeting of the Sections of Surgery and Tuberculosis at the Annual Meeting of the British Medical Association, Winnipeg, 1930.

application. This apparatus, for which nothing original is claimed, consists of three ordinary Winchester bottles with rubber stoppers pierced with two holes for glass rods, a flask for Dakin's solution, and some glass and rubber tubing (see figure), all of which may be obtained at any chemist's at small cost.

TECHNIQUE OF OPERATION

The operation is carried out under local anaesthesia. It can be performed quite readily in bed if the patient is too ill to be moved. In the case of infants and children a catheter size No. 16 or No. 18 (French) is inserted through a trocar between the ribs, and the trocar withdrawn. The opening around the catheter is then sealed by the application of successive layers of absorbent cotton saturated with collodion until a collar is built up around the tube, five inches in diameter, and about half an inch thick. This dressing is then fanned for half an hour before the patient leaves the table, when the collodion is sufficiently firm to allow of the child being moved without danger of disturbing the dressing. A clamp is left on the end of the catheter for four hours, when it is removed and the suction drainage connected. Irrigation of the cavity with Dakin's solution is begun the following morning. These irrigations are carried out every two hours during the day, and two or three times at night. The top of the fluid in the container for Dakin's solution is never allowed to be more than eighteen inches above the opening in the chest. To irrigate, the clamp is removed from the tube leading from the Dakin's flask and the solution allowed to run into the chest until it causes pain or stops running from equalization to pressure. This clamp is then replaced, and the clamp from the tube leading to the suction is removed, when the solution drains off into No. 1 bottle. If the catheter becomes plugged with fibrin, as sometimes occurs, it can usually be freed quite easily by disconnecting it from the drainage and injecting saline or Dakin's solution with a syringe.

The temperature usually goes down to normal in two or three days. The lung expands rapidly, and the amount of pus in the washings rapidly diminishes. After the washings have returned clear for five days, we consider that the cavity for practical purposes is sterilized, and if the lung has expanded satisfactorily and the general condition of the patient permits, the tube may be removed from the chest and dry dressing applied.

Though the majority of my cases have been concerned with children, I have also found this method equally satisfactory in adult empyema, and have treated two cases of subphrenic abscess, with results that were much superior to those obtained by the usual open method of treating that condition.

RESULTS

Forty-two cases of acute empyema in infancy and childhood were treated by this method. In twenty-two cases the infecting organism was the pneumococcus; in five cases the staphylococcus; in three cases the streptococcus. Six were reported "no growth," and in six cases no report could be found.

The following group shows the number of cases in each year of life.

Year	Number	Year	Number
1st	4	7th	3
2nd	7	8th	2
3rd	8	9th	3
4th	4	10th	2
5th	3	11th	1
6th	5		

The youngest child was aged 4 months, and the eldest 11 years. There were eleven cases among children in the first two years of life, and more than half the cases were in children of 4 years of age and under. Of the children in the first year of life, one was aged 4 months; one 5 months; one 6 months; and one 11 months. All of them recovered.

The average number of days of drainage was 25.66. This includes all days in which there was drainage from the empyemic cavity.

There was one death, making a mortality of 2.38 for the series. This occurred in the case of a child, aged 14 months, who developed empyema following broncho-pneumonia. The child's condition was extremely grave when first seen. Vomiting and diarrhoea were present, and persisted until death. The chest was first aspirated and then drained by the usual method. The condition, however, gradually grew worse, and death occurred a week after the institution of the closed drainage. The infecting organism was the pneumococcus. It was found on necropsy that the child had developed pneumonia in the other lung, and that acute pericarditis was also present.

There was one case of pleural shock. This occurred while irrigation of the cavity was being carried out by an inexperienced nurse, who allowed the Dakin's solution to continue to run into the thorax after the child began to scream with pain. Contrary to regulations, the container holding the Dakin's solution had been placed nearly three feet above the opening in the chest, instead of the required eighteen inches. The child gasped for breath, and rapidly became cyanosed, with weak and rapid pulse, and presented the appearance of impending dissolution. When an attempt was made to siphon off the Dakin's solution, it was discovered that the catheter was blocked. I happened to be in the hospital when the accident took place, and at once removed the tube from the chest and allowed the contents of the pleural cavity to escape. Some improvement took place at once. Suction was again applied, and the child went on to recovery, though its condition for some six to eight hours was extremely grave.

There were two cases of pocketing—one in a child aged 6 months, and the second in a child of 2½ years. In both cases the secondary collection of pus was discovered while the child was still in hospital, and was drained in the usual way. In the first case a period of ten days, and in the second case of thirty days, was required for additional draining.

Three cases developed cellulitis of the thoracic wall, which, though not serious, was troublesome, and prolonged the convalescence. All three cases followed aspiration.

There were two cases of bronchial fistula. In one case the fistula did not interfere with the application of negative pressure. In this case irrigations were discontinued, and the fistula closed in two days. In the other case it was found impossible to maintain negative pressure. A small amount of Dakin's solution was allowed to run into the cavity twice daily, with the tube in the most dependent position, and immediately siphoned off. It was found that this could be done without provoking spasms of coughing. In this latter case the fistula closed in six days. Irrigations were then begun and negative pressure applied in the usual way.

With the exception of the two cases of pocketing there were no cases requiring secondary operations.

ADVANTAGES OF CLOSED METHOD

The advantages of the closed method over the open method fall under two headings—namely, mortality and morbidity.

Mortality.—The mortality under the closed method is lowered—in this series of cases to 2.38 per cent. The greatest reduction in mortality takes place in infants.

This reduction in the death rate can be attributed to the following causes: (*a*) the use of general anaesthesia is avoided; (*b*) surgical trauma is lessened; (*c*) the danger of secondary infection is greatly reduced.

Morbidity.—The period of illness is shortened, the average number of days of drainage being 25.06 days, while the average by the open method is six weeks. In my early cases the tube was left in the chest an unnecessarily long period; had these early cases been treated in the same manner as the later ones the average number of days of drainage would have been considerably reduced. This shortening of the period of drainage can be accounted for, first, by the action of the Dakin's solution in overcoming the infection and by its power of softening the exudate covering the lung surface, and secondly, by the assistance of negative pressure in expanding the lung and obliterating the cavity.

Another advantage of the method by no means unimportant is the elimination of the usual painful daily dressing, as anyone who has had experience with the open method of treating this condition in children can testify.

INTRANASAL DACRYOCYSTOSTOMY FOR RELIEF OF LACRYMAL OBSTRUCTION

AN ANALYSIS OF 63 CASES*

BY

F. HOLT DIGGLE, O.B.E., F.R.C.S.

HONORARY SURGEON TO THE EAR, NOSE, AND THROAT DEPARTMENT, ANCOATS HOSPITAL, MANCHESTER, AND TO THE MANCHESTER EAR AND THROAT HOSPITAL

The not infrequent failure of conservative treatment and the disappointments following extirpation or curettage of the tear sac for the relief of lacrymal obstruction have induced surgeons from time to time to attempt various methods in an endeavour to re-establish permanent intranasal drainage of the lacrymal apparatus.

HISTORY

With this end in view, the tear drainage apparatus has been approached surgically in three directions: (1) externally through the skin, (2) transantrally, that is, through the maxillary antrum, and (3) intranasally.

In 1904 Toti[1] described his external operation of "dacryocystorrhinostomie" in which, by an external incision, a communication is made between the lacrymal sac and the nasal passage. I have no personal experience of this method, but the best results are said to be obtained with large tear sacs, while there is some risk of injuring the delicate canaliculi. Mr. E. D. D. Davis,[2] however, prefers Toti's external operation, even in the presence of a suppurating sac or an external fistula, and finds it mechanically an easier and surer method than West's operation. Ten cases so treated were all successful. V. Eicken adopted a transantral approach, but the difficulties of the operation and the anatomical fact that the sac cannot be drained without removing some of the floor of the orbit soon prejudiced this method.

The intranasal route was first adopted by Caldwell in 1893, when he opened and drained the tear duct intranasally after a preliminary resection of the anterior end of the inferior turbinate bone. Similar attempts were made by Killian, Passow, and Okunoff. Between 1908 and 1910 West operated in seven cases, but he approached the nasal duct above the inferior turbinate body. He soon realized, however, that the obstruction lay at the junction of the tear duct with its sac and not at its lower nasal opening. Strazza in 1903 was the first to open the tear sac intranasally, but he did so by first exposing and opening the tear duct and tracing it upwards to the sac. To West[3] of Berlin, and to Dr. R. D. Paterson of Cardiff, belongs the credit of being the first to approach the sac directly. The operation of intranasal drainage of the lacrymal sac (intranasal dacryocystostomy) is therefore frequently termed "West's operation." J. S. Fraser of Edinburgh, who has done much to perfect this operation and place it on a sound basis, first performed it in 1915, and has recently[4] reported his results—seventy-five cures in eighty-nine West operations.

Between 1923 and 1929 I have, through the kindness of my colleagues on the staff of the Manchester Eye Hospital, performed seventy-nine West operations. The results, at least nine months after operation, have been traced in sixty-three cases. From a study of the records of these, an attempt has been made to obtain some information of the prospects of a permanent cure following intranasal dacryocystostomy, and also to ascertain the features that should guide us in making a selection of suitable cases.

TECHNIQUE

The success of the operation depends so much on its technique that, although the method has been so well described by West, Fraser, and others, a few details seem worth mentioning which from experience I have come to regard as important. Briefly stated, intranasal dacryocystostomy consists in the intranasal exposure and removal of the nasal wall of the tear sac, as it lies in the bony lacrymal groove, by removing the overlying nasal mucosa and bone. Anatomically, the lacrymal sac, in the majority of instances, is related intranasally to that region of the nose just in front of the anterior attachment and upper half of the anterior free border of the middle turbinal body.

Like Mr. Fraser I have abandoned local anaesthesia. The posterior margin of the frontal process of the superior maxilla, as it forms the anterior boundary of the lacrymal fossa, is occasionally too dense to remove comfortably with local anaesthesia alone.

About ten minutes before the induction of general anaesthesia the mucous membrane just in front of the anterior attachment and anterior border of the middle turbinate is injected with 1 per cent. novocain-adrenaline solution (2 to 3 minims of adrenaline to 1 drachm of 1 per cent. novocain), the nose having previously been well packed with the usual cocaine-adrenaline gauze. The local ischaemia thus produced is a distinct advantage, though in a few instances, in spite of this injection, troublesome haemorrhage has considerably increased the difficulties of the operation.

Anterior middle turbinectomy was performed in only nine cases. It should be avoided, unless absolutely necessary to gain access, as the persistent oozing of blood tends to obscure the field of operation. Anatomically it is rarely demanded, since Thorsch and others have demonstrated that in fully 65 per cent. of cases the middle turbinate body lies behind the lacrymal groove.

The nasal wall of the tear sac should be thoroughly exposed by a liberal removal of the overlying bone, otherwise granulations growing from the cut bony margins will, in course of time, coalesce and completely occlude the new ostium. I have found a long narrow and slightly curved chisel more effective and easier to manipulate than a gouge; in fact, I rarely use the latter, except, perhaps, to trim the margins. Having exposed the bone of the lacrymal fossa intranasally by the removal of a square-shaped piece of mucous membrane, I proceed to remove it in one piece. Three incisions with the chisel are made at the extreme anterior, upper, and lower boundaries of the exposed bone. They are joined anteriorly, while

*A paper read before the North of England Ophthalmological Society, October, 1930.

posteriorly the transverse incisions pass through the posterior margin of the frontal process of the superior maxilla. Each of the three bony incisions is deepened to the outer periosteum, and the outward penetration of the chisel is judged by placing the fingers of the left hand over the lacrymal fossa externally. I prefer to use my own fingers than to rely on those of an assistant.

In making these incisions the chisel is applied in the correct position under vision, and while held thus in the right hand is struck with the mallet by an assistant. With a fairly strong nasal raspatory, passed through the anterior incision, the square-shaped piece of bone thus delineated is separated from its outer periosteum and prised out of its bed by a leverage movement. The separated bone can then be lifted out of the nose with a pair of fine Luc's forceps, which may also be used to remove the thin lacrymal bone, or any other surrounding spicules of bone, until there is adequate exposure of the tear sac.

After trying many methods and instruments to remove the inner sac wall—often the most difficult step in the operation—I have found Paterson's long tenaculum forceps, specially designed for this operation, to be the most satisfactory. A fine lacrymal probe passed along the lower canaliculus makes the tear sac " tent " inwards. It is then seized with the tenaculum forceps drawn inwards, and on removal of the probe the protruding portion of the sac wall is excised with a long slender and very sharp knife, applied as close to the outer nasal wall as possible. If necessary, the opening thus made can be further enlarged by piecemeal removal with biting forceps of the Grunwald pattern. This, I find, is by no means easy with thin-walled sacs, for, when once the sac is opened and its contents have escaped, it is difficult to engage the blade of the biting forceps in the lips of the opening.

The opening into the sac should be large, and in my opinion should be at the most dependent part of the sac, otherwise tears will tend to collect in the lower part of the sac and keep up a certain amount of suppuration. To make the opening as dependent as possible I cause the lowest part of the sac to " tent " with the lacrymal probe before excision by raising the outer part of the probe when its inner end is engaged in the sac. The efficiency and size of the opening should be tested by washing out the sac with a syringe and cannula, the point of the cannula being inserted only just inside the lower canaliculus. If the fluid tends to regurgitate through the upper puncture, though it may also be entering the nose, or if there is any obvious swelling of the sac, or even if fluid can be further expressed from the sac after syringing, the opening needs further enlarging. Time taken in ensuring an adequate opening is well spent.

AFTER-TREATMENT

Tamponage of the nose with gauze should be avoided, unless absolutely necessary to control haemorrhage, since, in my opinion, it is apt to seal together the lips of the opening in the sac wall. On the second day the sac can be gently cleansed with saline solution, and this should be repeated, if the sac contains much pus, every second day for ten to fourteen days. The cannula should only just be engaged in the lower canaliculus, and not passed into the sac or even pushed through the artificial ostium into the nose. Lavage not only cleanses the sac of pus, but it prevents dried blood accumulating around the lips of the artificial ostium, which from organization and cicatrization might tend to promote its stenosis, or even complete closure. No special intranasal medication is required other than spraying the nose once or twice daily for the first ten days with a simple menthol and paroleine solution.

RESULTS OF WEST'S OPERATION

Of the 63 West operations which have been traced, 46 (73 per cent.) were completely successful—that is, the epiphora was completely cured, even when the patient was out of doors ; there was, of course, no enlargement of, or suppuration in, the sac. Six of the remaining 17 cases may perhaps be regarded as moderate cures in that, although there was some slight epiphora out of doors, there was no longer any distension of the sac or recurrent attacks of acute dacryocystitis. In each of these six cases persistent epiphora and dacryocystitis had been a source of real discomfort to the patients, four of whom considered they were really cured.

Eleven (17 per cent.) were absolute failures. A brief survey of the case records of these patients may indicate the cause of failure. Four gave a history of recurrent dacryocystitis ; in two of these it was noted in the case records that considerable difficulty was experienced in passing the lacrymal probe along the canaliculus, a kinking of the canaliculus being suspected. Severe bleeding, obscuring the field of operation, was mentioned in three cases, while in four there was no apparent cause. My second West operation was performed in one of these cases ; two others were apparent successes two or three months after operation, but later were complete failures. Presumably an inefficient removal of bone with subsequent stenosis was the explanation.

In 1925 Mr. J. S. Fraser[5] reported 73 per cent. of cures, and four years later 75 per cent. in a series of 89 West operations. A cure rate, therefore, round about 73 to 75 per cent. is, I think, the experience of all those who have essayed the procedure on any large scale.

GENERAL PRINCIPLES IN SELECTION OF SUITABLE CASES

The age of the patient, the size and width of the nose and its nasal passages, will generally be the determining factors whether a case is suitable for a West operation or not. Obviously there must be sufficient room to gain access so that delicate and difficult intranasal surgery can be performed under clear vision. An enlarged middle turbinate, or a nasal septum deviated to the side of the lesion interfering with adequate access, can be easily overcome by a partial turbinectomy and by a submucous resection operation respectively. Anterior middle turbinectomy, for reasons already given, should be avoided as far as possible. For large hypertrophies completely preventing access, I now prefer to remove the superfluous tissue under local anaesthesia a few weeks before resorting to the West operation. A submucous resection of the nasal septum which was found necessary in 11 cases was done as a preliminary under the same anaesthesia. If adequate access is at all doubtful, a resection of the nasal septum is always worth while, as the additional room gained is considerable. Some surgeons have advocated a transseptal approach to the tear sac—when operating, for example, on the right sac, to approach it from the left nasal passage through the nasal septum after resecting the cartilage. I have not yet had occasion to do this, as the additional room provided by a resection of the nasal septum has given adequate access.

A West operation should not be attempted in the presence of active lupoid or syphilitic disease of the nose, for obvious reasons. Hypertrophic or atrophic rhinitis (with or without ozaena) does not *per se* prejudice a successful result. Suppuration in a nasal sinus, particularly if any of the anterior group is involved, should first be corrected. In a paper read in the Section of Ophthalmology at the Annual Meeting of the British Medical Association in 1927,[6] I referred to the relationship between nasal sinus infection and lacrymal obstruction,

and reported two interesting cases of closed ethmoidal empyema which had been completely cured of epiphora by drainage of the ethmoidal labyrinth alone. The incidence of nasal sinus infection in lacrymal obstruction, as was shown in that communication, is, however, rare, and I do not wish to convey the impression that the cure of suppuration in an interior nasal sinus will always relieve epiphora.

It is of course essential to ascertain before the operation that there is no abnormality or stenosis in the puncta and canaliculi, otherwise an artificial intranasal opening of the lacrymal sac will spontaneously close if tears are unable to flow along the canaliculi. If Bowman's operation (slitting of the lower canaliculus) is accurately performed, it would not seem to preclude a successful result, as was indicated in four cases in the present series.

In regard to the lacrymal sac an external sinus discharging at the time of the operation, provided it is not acutely inflamed, does not of itself prejudice a successful West operation. The sinus should be gently scraped with a fine curette and a very light dressing applied. This was done three times in the present series with successful results in each case. If the sinus is acutely inflamed, external drainage should be maintained until all inflammation has subsided.

Occasionally pressure with the finger over the sac causes its contents to flow into the nose rather than along the canaliculus, although epiphora and distension of the sac may be present. Fraser considers that a West operation in these circumstances is not likely to be so successful. In the present series such a condition was noted in five cases, two of which were failures. While the figures are interesting, they are obviously too small to furnish any conclusions.

There can, I think, be no doubt that the operation is relatively easier with thick-walled than thin-walled, scarcely palpable sacs; yet in the present series of 63 West operations the consistency of the sac wall would of itself seem to have no bearing on the end-result. The consistency of the sac was recorded in 45 cases—namely, thin-walled in 11 and thick-walled in 34. Unsuccessful West operations were performed on three (approximately 27 per cent.) of the thin-walled sacs and 10 (29 per cent.) of the thick-walled sacs. Other factors, such as recurrent acute dacryocystitis with possible cicatricial kinking or inflammatory stenosis of the canaliculus, a history of which was obtainable in the majority, no doubt prejudiced a favourable result in what was, apart from the consistency of the sac, an easy operation.

Intranasal dacryocystostomy should not be attempted when the tear sac is acutely inflamed. The inflammatory condition must be treated on the usual lines by an external incision, if necessary, and at least six weeks should elapse after subsidence of the acute phase before resorting to a West operation. Excessive bleeding otherwise adds considerably to the difficulties of the operation, while there is the added risk of exciting a serious spreading septic osteomyelitis of the facial bones.

I have the impression that recurrent attacks of acute dacryocystitis with abscess formation, which have either spontaneously discharged externally or been incised, prejudice a successful result. The sac wall is often very firm and thick; the contents of the sac cannot be expressed either along the canaliculi or into the nose; and there is occasional difficulty at the operation in passing the lacrymal probe into the sac. It is interesting to note that such a history of recurrent dacryocystitis accounted for four of the eleven complete failures. A history of dacryocystitis, however, either single or recurrent, occurred seventeen times in the total series of 63 West operations, eleven successes, two moderate results, and four failures being recorded. None of the patients with successful or moderate results had, however, had more than one attack of acute dacryocystitis. It would appear, therefore, that, although a single attack of acute dacryocystitis does not prejudice a successful issue, yet recurrent inflammations producing thick-walled sacs, perhaps loculated with malformation, kinking, or inflammatory stenosis of the canaliculi, though not a definite contraindication, are not so likely to yield successful results.

RECONSTRUCTION OF THE FOREARM AFTER AMPUTATION OF THE HAND

BY

ARNOLD K. HENRY, M.B., F.R.C.S.I.

PROFESSOR OF CLINICAL SURGERY, FACULTY OF MEDICINE, CAIRO

(From the Surgical Unit, Kasr-el-Aini Hospital, Cairo)

In 1928 I described an osteoplastic operation, performed in the previous year; my object was to make the forearm prehensile after complete loss of a hand.[1] My first patient was an Egyptian policeman whose left hand had been cut off in a tramway accident, and in December, 1928, one and a half years after the operation, he demonstrated the strong and adroit function of his reconstructed limb before the Surgical Section of the International Congress of Tropical Medicine. This result encouraged me to repeat the reconstruction at the first opportunity, and in the same year, through the courtesy of Professor Ali Bey Ibrahim, who sent me the case, I performed a similar operation, this time on the right forearm of a boy aged 8 (Fig. 1).

AIM OF THE OPERATION

The aim is to make a new digit provided with bone, tendinous attachments, and skin, and nourished by the radial trunk; this digit is allowed to become ankylosed with the shaft of the radius at such an angle that the movement of pronation brings it into firm contact with a stiff artificial finger attached to a gauntlet fitting the stump; grip and its relaxation are thus secured by pronating and supinating the forearm.

The initial difficulty was to obtain an aseptic field in the granulating stump, and I knew that if I discharged the boy from hospital to live down latent infection, his family would soon be content to leave his forearm useless. For this reason I tried, as I had tried in my first case, to rid the unhealed stump of sepsis by means of the high-frequency current. In neither patient was this attempt entirely successful, but the subsequent reaction in both was mild, and did not harm the new digit.

THE OPERATION

I repeated the two-stage procedure of the first operation at one sitting.

Stage I.—With sparks from the high-frequency apparatus, I began by charring the granulations of the stump, and also an inch-wide margin of skin. I then coagulated the region of the carpus; the limb was cleaned afresh with ether and a 5 per cent. solution of picric acid in alcohol, and after a change of gloves and instruments I began the second stage of the operation.

Stage II.—A circular disarticulation dividing the skin just distal to the radial styloid removed the remains of the

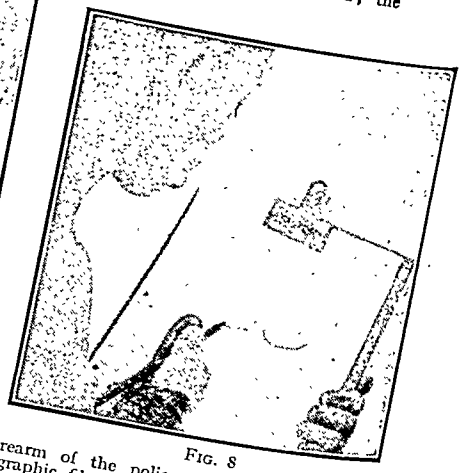

FIG. 8

FIG. 8.—Enlargement taken from a cinematographic film to illustrate the function of the reconstructed forearm.

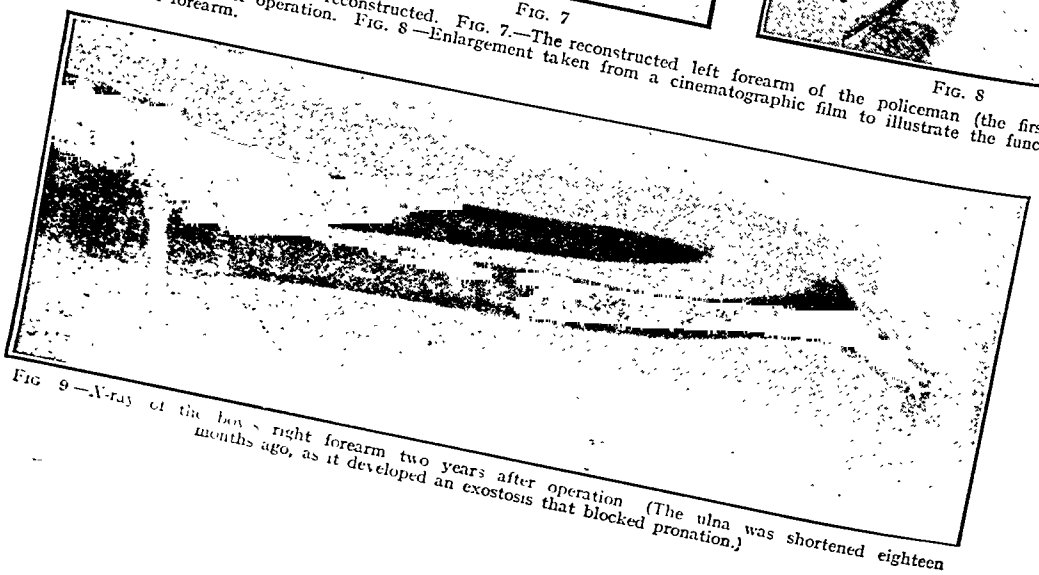

FIG. 9.—X-ray of the boy's right forearm two years after operation. (The ulna was shortened eighteen months ago, as it developed an exostosis that blocked pronation.)

carpus. I then made two longitudinal incisions on the forearm, one in the mid-line of its flexor aspect, the second on the dorsal side, a fingerbreadth radial to the middle line. Owing to the small size of the child's limb each incision was only 3 inches long, while in the man's the measurement was 5 inches. In order to provide a web at the base of the new digit, both incisions approached the ulna at their proximal ends; both were deepened to the bone—the volar incision between the tendon of the flexor carpi radialis and the flexor tendons of the fingers, the dorsal between the radial extensors of the wrist and the common extensors of the fingers. Special care was taken to mobilize and retract the bellies of the abductor pollicis longus and the extensor pollicis brevis which crossed the line of incision. The periosteum of the radius was divided longitudinally, and, with a fine saw, a 3-inch rod, a quarter of an inch square in cross-section, was separated from the distal third of the radial shaft on its lateral side. I find it a mistake to use a motor-driven saw for this purpose; the force of its revolution tends to tear the bony rod out of its periosteal covering, an accident that happened in my first case, though fortunately without causing the rod to necrose. [Ligatures tied round the rod as the saw-cut is deepened reduce the risk of enucleation (Fig. 2). The base of the rod should be incompletely separated, by greenstick fracture, from the shaft.] The tendon of the flexor pollicis longus, the radial artery, and the tendon of the flexor carpi radialis were next transferred *en bloc* to the flexor face of the bony rod; the dorsal face carried five tendons, the brachioradialis insertion, and, fastened to the rod with catgut, four tendons—the two radial extensors of the wrist, the short extensor, and long abductor of the thumb (Fig. 3). [These tendons, after re-education, become pronators and supinators, and act powerfully because they are attached to projecting bone.]

The radial skin-flap (Fig. 4) was stitched round the new digit (Fig. 5), and the ends of the ulnar and radial shafts were shortened sufficiently to allow the ulnar skin-flap (Fig. 4) to be turned over them like a hood, the edge of which was sutured to the raw edge of skin at the root of the new digit, thus completing the web between the digit and the stump (Fig. 5). The new digit was then splinted at an angle to the volar face of the forearm. In this way the limb, as in my first case, was provided with an extremity shaped somewhat like the small glove used in prize fights (Figs. 6 and 7). To this it was my intention, in the boy's case, to add a second digit, made from the ulna, instead of completing the grip by means of an artificial finger; the skin of the child's limb, however, was insufficient for this purpose.

AFTER-TREATMENT

This was begun as soon as an *x*-ray showed that the new digit was ankylosed with the radius (Fig. 8). The forearm was then fitted with a temporary prosthesis made of plaster-of-Paris that bore a "finger," against which the new digit was carried by the movement of pronation; this afterwards served as a model for the definitive apparatus.

My first patient used a strong leather gauntlet, stiffened with lateral plates of metal and laced to his forearm, for more than a year; at first this was quite satisfactory, but in time it worked loose and began to turn round when the new digit pressed on its artificial opponent. To avoid rotation of the gauntlet I had it fixed to a leather arm-piece by means of two lateral plates hinged at the elbow. Both patients now wear this improved form of prosthesis.

The use that the second patient makes of his reconstructed forearm is shown in one of the enlarged extracts from a cinematographic film that illustrates this paper (Fig. 8).

For the skilled movements of both patients I am indebted in a special degree to Miss Gwillim, sister-in-charge of the re-education and massage department, Kasr-el-Aini Hospital, and my thanks are due to my colleague Dr. R. A. Gardner, director of the department of radiology, for his *x*-rays. The improved gauntlets were made for me by Mr. A. Moring of Cairo.

PUERPERAL COMA: RAPID RECOVERY FOLLOWING INFLATION OF BREASTS

BY

J. G. KININMONTH, M.D.Ed.

HOVINGHAM, YORK

The following case is recorded, partly because of the rather unusual treatment adopted, and partly to draw attention to the possibility of the occurrence in puerperal women of a condition analogous to milk fever in cows.

A primipara, aged 21, with nothing of note in her previous history, was first seen early in September, 1930. Her pelvic measurements were normal, the foetus was presenting by the vertex, and nothing unusual was found in the urine. Labour commenced about 5 a.m. on September 24th, and delivery was accomplished on the following day at 12.30 a.m., the head, which was in an occipito-posterior position, having been rotated manually and extracted with forceps. The child, a full-time healthy male, was alive, and there was no perineal tear or laceration of the vaginal walls. During the next forty-eight hours progress was satisfactory, but on the night of September 26th the patient was disturbed by nausea and vomiting. This continued next day, but her temperature remained normal until 6 p.m., when it rose to 101° F., the pulse rate being 128. She then looked very ill and complained of epigastric pain. Nothing abnormal was detected on physical examination, and she had a fairly good night after a dose of chloral and bromide. On the morning of September 28th the temperature was 100.5° and the pulse 110; she looked unwell and had a flushed face and slight icteric tinge of the conjunctivae. Her mental condition was normal. On examination some tenderness was felt over the liver; the uterus was not specially tender, and appeared to be involuting normally; the lochia were also normal. She was given glucose salines and later glucose by the mouth, and vomited twice only during the day. She was seen again at 8 p.m., when her temperature was 98°, and the pulse 100. She had been asleep and seemed dazed; she did not answer when spoken to, but this was attributed to her sleepy condition. At 4 a.m. on September 29th she was found to be in a very stupefied condition, her speech being unintelligible. The temperature was 102.8°, and the pulse 140. Her condition was so alarming that 0.5 c.cm. of pituitrin, and a rectal saline, were given. When seen half an hour later her pulse had improved considerably, but she was almost completely comatose. At 11 a.m. her temperature was 100°, and her pulse 120; she was jaundiced and practically in a state of coma, resenting only the most painful stimuli and being quite incontinent of both urine and faeces. There was a slight froth at her lips, and she dribbled saliva, though she usually swallowed fluid placed in her mouth. The tongue was moist, the eyes were open and occasionally rolled about, but apparently she did not see. The pupils were widely dilated, but reacted to strong light. Knee-jerks and ankle-jerks were present and equal; there was no clonus, and the plantar reflex was flexor. Nothing abnormal was detected in the chest. A vaginal examination was made, but nothing abnormal was found. An intracervical swab yielded a scanty growth of diphtheroids and *Bacillus coli*, but no streptococci or other pyogenic organisms. A catheter specimen of urine was found to contain numerous pus cells, and gave a pure growth of *B. coli*. It also contained bile and a trace of albumin, for which the pus cells would account. There were no leucin or tyrosine crystals. A leucocyte count showed: white blood cells 27,900, polymorphs 84 per cent., lymphocytes 10 per cent., monocytes 6 per cent., no eosinophils or basophils being seen.

The condition remained much the same throughout the day, during which 30 c.cm. of antistreptococcal serum was given. During the night she was rather restless, and cried out occasionally "like a meningitic." Next morning (September 30th) she was much more restless than on the previous day, and tossed about the bed. She still took no notice of questions or of her surroundings, and was still incontinent and dribbled saliva, but took fluids fairly well. Her temperature at 11 a.m. was 100°, pulse rate being 128. At 7 p.m. she was seen by Professor Oldfield, her condition

then being unchanged from the morning. He thought that the condition might be analogous to "milk fever" of cows, and suggested mammary inflation. This was carried out with a sterile Higginson syringe attached to an exploring needle, which was thrust well into the breast substance. The nipples were tied off with tape, since, before this was done, air was observed bubbling through milk which had been expressed on to the surface. Both breasts were inflated as far as possible, though great tension was impossible on account of spreading surgical emphysema. Two hours later she made a motion of assent when asked if she would like a cup of tea—the first sign that she had understood a question for forty-eight hours. On the morning of October 1st she was conscious and rational, though childish. She spoke rather thickly and with difficulty, but this may have been due to the surgical emphysema which had spread up her neck, to the lower jaw on either side, and down over her abdomen. Her temperature was 99.5°, and the pulse 100; the jaundice was much less. The following day she was perfectly clear mentally, no longer childish, and looked and felt quite well, though her temperature was 100°, and there was still pus in the urine. Thereafter progress was very satisfactory, for, though during the next week her temperature occasionally went up to 100° and pus remained in the urine, she ate, and felt perfectly fit. Recovery was complete by October 20th.

COMMENTARY

The case was clearly a toxaemia of an unusual kind arising during the puerperium. The clinical picture was unlike puerperal sepsis, eclampsia, acute yellow atrophy, or delayed chloroform poisoning, but resembled "milk fever" which occurs in cows. The remarkable recovery after mammary inflation makes milk fever as likely a diagnosis as any. The pyrexia can be accounted for by the *B. coli* infection, which was probably incidental to, and not the cause of, the extraordinary cerebral condition. It is unlikely that the case is unique; some of the cases described in hospital reports as "coma without fits" are probably really cases of "milk fever."

This condition occurs in cows two or three days after calving. The animal is noticed to be uneasy and unsteady on its feet, falls and is unable to rise, and rapidly becomes unconscious, with dilated pupils, stertorous breathing, and dribbling saliva. The heart rate is increased, but the temperature is always subnormal unless some febrile complication is present. Without treatment 30 per cent. are said to recover spontaneously, the remainder die. About thirty years ago, inflation of the udder was found to have an almost miraculous effect in these cases; from a comatose and apparently fatal condition the cow completely recovers within eight hours. This treatment—until lately purely empirical—has reduced the mortality from milk fever to practically *nil*. A condition similar to that found in the cow occurs in the mare, the ewe, the sow, the goat, and the bitch, but it does not appear to have been described in woman.

It has been recently shown by Russell Greig[1] that milk fever is associated in every case with a marked hypocalcaemia, and that recovery following inflation is accompanied by a rise in the blood calcium to normal. Recovery can also be brought about by the injection, intravenously or subcutaneously, of calcium gluconate. According to him the acute blood calcium deficiency—the essential cause of milk fever—is the result of an inefficient parathyroid mechanism which is unable to cope with the drain on calcium resulting from the establishment of lactation. The specific effect of mammary inflation is apparently due to the mechanical distension preventing further interchange of calcium from the blood to the gland acini and possibly causing a reabsorption of calcium from the gland. Unfortunately in the case reported no blood calcium determination was done, and it is therefore impossible to identify precisely the condition present with milk fever.

I wish to express my thanks to Professor Carlton Oldfield, at whose suggestion the mammary inflation was done, for his very valuable help in this case.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

TETANUS: UNUSUAL CHANNEL OF INFECTION

In view of the unusual channel of infection the following case of tetanus may be of interest.

A man, aged 58, was admitted on December 28th, 1930, complaining of cramp-like pains throughout the body, and stiffness of the face, jaw, and legs. He could talk and swallow only with difficulty. Examination confirmed this stiffness, and while being observed the patient had several mild tetanic spasms. Careful search revealed no wound, but he had a chronic varicose ulcer of the right leg, which was fairly clean. The blood pressure was 185 mm., and the urine contained many granular casts. The blood non-protein nitrogen was 60 mg. per cent. The case was diagnosed clinically as tetanus, and large doses of antitetanic serum were given intravenously. The patient died suddenly on December 30th.

Post-mortem findings were largely negative, except for some chronic nephritis. Two pieces of the ulcer were removed and incubated in meat medium. On the fifth day many bacilli bearing terminal spores were seen. The culture was then submitted to Dr. T. B. Davie of the Thomson Yates Laboratories, University of Liverpool, who reported as follows. "Subcultures from your original meat medium culture showed very numerous streptococci, and among other organisms a few terminal spored organisms. Anaerobic cultures showed chiefly, and in large numbers, *B. welchii*, and a moderate number of terminal sporing organisms, most of which, however, appeared to be the non-pathogenic frequenter of wounds—Hibler's bacillus—but a few appeared to resemble *B. tetanus*. Animal inoculation: two guinea-pigs were inoculated with the mixed anaerobic culture. Both were given protection against *B. welchii* (anti-gangrene serum), and one against *B. tetanus* as well. The latter guinea-pig is still healthy, the other has developed pathognomonic extensor spastic paralysis. *B. tetanus* thus proved present."

It is interesting to note that the man's occupation was that of a fish frier, and it is quite likely that the source of infection was the soil from the potatoes used in that trade.

My thanks are due to Dr. Davie for the great trouble and care taken in investigating the culture, and to Dr. H. H. MacWilliam for permission to publish the case.

W. S. BRINDLE,
Liverpool. Assistant Medical Officer, Walton Infirmary.

MELAENA NEONATORUM

The report in the *British Medical Journal* of August 9th, 1930 (p. 213), of a case of melaena neonatorum prompts me to record the occurrence of a similar case accompanied by albuminuria of pregnancy in the mother.

For three weeks before her first confinement a primigravida, aged 29, had marked albuminuria; the systolic pressure was 150 mm., and there was no cardiac hypertrophy. On an average 75 oz. of urine were passed in the twenty-four hours; her temperature was normal, and she complained of no toxic symptoms. With rest in bed, restricted diet, and eliminative treatment the albuminuria was considerably reduced before the onset of labour. At 8 a.m. on February 2nd the patient was delivered of a female child weighing 7 lb. The labour was prolonged owing to the presentation being

right occipito-posterior, and delivery was effected by forceps and chloroform-ether anaesthesia.

On the first and second days the baby vomited a little bile-stained fluid, and at 7 p.m. on the second day (February 3rd) passed per anum more than a tablespoonful of bright red blood mixed with clots. The following day all the napkins were soaked with black tarry material. The baby continued on three-hourly breast feeds; no further vomiting occurred, but it became pale, with parched lips and tongue.

Since the melaena continued, 10 c.cm. of blood were withdrawn, on February 5th at 11 a.m., from one of the veins of the father's arm, and rapidly injected into the baby's buttock. No further bleeding occurred, and five weeks later, when the baby was vaccinated, it appeared to be in perfect health.

The puerperal history of the mother was uneventful, except for slight post-partum haemorrhage on the seventh day, which cleared up in forty-eight hours with the administration of ergot. By February 26th she had resumed her usual housework, and was albumin-free. No history of haemophilia was elicited from either of the baby's parents.

Subsequently a colleague told me of a case of melaena neonatorum which recovered after the injection of anti-diphtherial serum. From this it would appear that the essential factor in treatment is to supply thrombin, or the so-called fibrin-ferment contained in blood serum, either by injecting serum or by forming an intramuscular haematoma, which would, conceivably, produce local serum formation in the infant's tissues.

SOUTHAMPTON DIVISION

Treatment of Rheumatic Disease by Heat

A general meeting of the Southampton Division was held at the Royal South Hants and Southampton Hospital on January 28th, when Dr. R. FORTESCUE FOX addressed the members on the treatment of various types of rheumatic disease by heat.

Dr. Fortescue Fox began by remarking that of recent years one objective of treatment in chronic rheumatic disease had been strongly emphasized in this country—namely, the elimination of infective foci. He himself believed that infection did not by any means account for the causation of rheumatism, and that other forms of treatment were imperatively necessary in most chronic cases. La Ligue Internationale Contre le Rhumatisme, of which he was president, had put forward a rather comprehensive conception of etiology. Four possible factors to be borne constantly in mind had been defined by van Breeman as follows: (1) cosmic or external influences, such as climate, occupation, and traumatism; (2) conditions of the skin and circulation; (3) constitutional abnormality; (4) infection.

Confining himself generally to the external causes operating upon the surface of the body, Dr. Fox said that the healthy person's tolerance of external cold was sometimes cited to throw doubt upon the fact that persons in ill-health were extremely sensitive to changes of temperature. The sturdy, cold-bathing Englishman found it difficult to understand that some rheumatic subjects might be seriously chilled by dressing or undressing in an unwarmed bedroom. Healthy persons lived with comfort through an English winter at a temperature about 50 degrees below blood heat, and equally found a tropical temperature of 130 degrees not insupportable. The ability to resist climatic cold depended on the generous production of body heat, just as the ability to resist external heat depended on the power of rapid cooling by radiation and perspiration. The fundamental connexion between the thermal balance of the body and disease was apt to be forgotten. A local or general elevation of temperature was the normal reaction to the invasion of pathogenic organisms. Conversely—a fact of perhaps equal significance—many chronic diseases, such as old tuberculosis, were associated with depressions of temperature, local or general. Subnormal temperatures might be associated with poor digestion, poor circulation, and nervous depression, and they were common in old age and among otherwise healthy sedentary people. The main elements of climate—temperature, air movement, and moisture—were usually combined in their action upon the human body. Consequently, the organism reacted, not to a single impression, but to a constantly changing combination. The loss of the body heat was increased by moisture, as in cold mists, owing to the great capacity of aqueous vapour for absorption of heat. The cooling of the body by exposure in temperate climates was wholly beneficial to health; but, on the other hand, when heat production was deficient, from ill-health, the cooling process must be correspondingly reduced.

After making the inference from the work of Elsworth Huntingdon on optimum temperatures, that the ideal mental climate corresponded to the English winter, and the ideal physical climate to the English summer, Dr. Fox pointed out that as medical men they must not consider normal subjects. The temperature of London in January was undoubtedly stimulating to persons in vigorous health, but the mean temperature of an English summer, with its more even warmth, and only moderate variations of wind and weather, was much more favourable to lowered conditions of health. Everyone knew the relief of fatigue that followed a brief hot bath, and nothing compared with heat for the relief of pain, tension, and vascular stasis. Heat could be made to undo the effects of cold, of traumatism, and even of septic invasion and inflammatory reaction. Its proper application allayed functional disturbances, restored the warmth of the body, and increased and equalized the circulation of the blood. There could be no question that the systematic use of thermal agencies had a wide field of usefulness in preventive and curative medicine.

The word "rheumatism" signified an undifferentiated group of diseases, whose scientific classification awaited an accurate knowledge of causation. Many cases described as "rheumatic" were affected in one way or another by cold and heat. One stigma of rheumatism was a defect of the capillary circulation in the skin, set up by the recurrent irritation of cold and other climatic factors. When the irritability was sufficiently prolonged, an autonomous capillary spasm was set up, and later a stasis in the lymph spaces. True rheumatism, therefore, appeared to be a disease in which, following on circulatory spasm and stasis in certain capillary areas, structural changes supervened, such as fibrositis, as a result of continuous or repeated irritation. To this, and to various subsidiary factors, such as food irritants and infective organisms, must be added a constitutional abnormality in the response to external cold. This explained the curative effect of treatment by heat and induced hyperaemia, also elimination, endocrine therapy, and treatment having for its object the restoration of the normal reaction to cold. This definition separated from a mass of diseases the category which he would call true or capillary rheumatism, a category from which the acute disease known as "rheumatic fever" must be ruled out, as well as other forms of specific arthritis.

Dr. Fox then examined singly the methods of applying heat in England, supposing that a change to a warmer climate during the colder months of the year was not possible. The hot vapour bath, in which the air was

supersaturated with moisture, and which was accompanied by mechanical stimulation and followed by cold, was the best preventive treatment for catarrh and rheumatism. Sedative baths, combined with immobility and rest—for example, warm air at 95° F., softened by vapour from hot water—had the effect of removing impurities, softening the hard epidermis, and gradually restoring the natural action of the skin, without undue heat or excitation. These were most valuable in sciatica, lumbago, muscular rheumatism, and in nearly all forms of painful arthritis and fibrositis. Where pain was localized, local vapour baths or douches were effective. Dr. Fox added that rheumatic patients, heated by baths, should not be allowed to cool down to their former temperature. An artificial climate should be provided and maintained over a period of three or four weeks. The great difficulty in treating rheumatic disease in a cold climate was intercurrent cooling, which checked the increase of circulation effected by the bath. A third means of treatment was a movement cure in subthermal moisture and heat (95° to 100°). This included immersion and manipulation in pools, as well as warm manipulation douches, like those of Buxton, Bath, and Aix-les-Bains. Such treatment had its principal indications in the chronic rheumatic affections of middle life—climacteric arthritis, and congestive and toxic conditions, formerly described as "gouty." A stimulant thermal cure, like the brine bath at Droitwich, was beneficial in most cases of rheumatism that had passed the acute stage. It provided a general mild, counter-irritant action of the skin, usually combined with gentle movements, and was indicated in convalescence from infective arthritis and in chronic sciaticas and lumbagos. He was of opinion that the salt cure in England should be systematically developed in its application to rheumatic disease. Finally, hyperthermal applications of various kinds, such as volcanic muds, peat, melted paraffin, and whirling water, raised the temperature of the affected part several degrees, powerfully stimulated the arterial circulation, and in favourable cases resolved long-standing deposits and swellings.

In conclusion Dr. Fortescue Fox recapitulated his scheme of treatment as follows:

(*a*) For preventive treatment: the very hot vapour bath.
(*b*) For acute and painful states: sedative heat and moisture, general and local, with rest and no movement.
(*c*) For the rheumatism of middle life: a sedative warm movement cure; manipulation in douches and pools.
(*d*) For more advanced cases: surface stimulation; salt baths, with cautious movements.
(*e*) For unresolved and old-standing arthritis and osteo-arthritis, climacteric and senile: hyperthermal applications.

All these modes of treatment operated upon the body as artificial climates. They should be taken by preference in the autumn and early spring, and generally be combined with eliminative treatment; further, in an English climate, the patient must be maintained in a thermal environment, so as to secure the cumulative effect of heat, during the whole period of his cure.

Reports of Societies

INDOLENT ULCERS OF THE LEG

A meeting of the Medical Society of London took place on February 23rd, with Dr. R. A. YOUNG, president, in the chair.

Mr. DICKSON WRIGHT brought forward for discussion the subject of indolent ulcers of the leg and their treatment. This was a common disease, and caused a good deal of suffering, disability, and economic loss. Vascular equilibrium in the leg could be lost owing to a number of causes. These cases were almost invariably known as varicose ulcers, but "gravitational ulcer" was a more comprehensive description, and had the merit of indicating the line of treatment which led to successful results. Among the causes of the development of ulceration were occupations involving long hours of standing, also the effects of pregnancy, venous obliteration of all kinds, lymphatic obstruction, severe trauma of the leg necessitating long rest in bed (as in fractures) ankylosis of the joints, especially the hip-joint, and senile vascular changes affecting the veins rather than the arteries. Bodily habitus was of some importance; the obese and the very tall were prone to develop very stubborn ulcers, and there were obvious reasons why these individuals had difficulty in the venous return in the leg. Gravitational ulcer was associated with a number of other pathological conditions, some of them due to disturbance of the vascular equilibrium and others to the presence of the ulcer itself. Every structure in the leg, from the bone marrow to the hair follicles, suffered changes due to inadequate nutrition. The pigmentation, which was the rule, was due to a mixture of altered blood extravasation and tattooed dirt. Abnormalities of the foot were usually secondary to the ulcer; it was rare to find an ulcer with a normal foot. Talipes equinus was a common deformity. Malignant disease supervened in a small number of cases, a certain sign of this being the invasion of the bones by the growth. The incidence of this complication was fifty times greater in the male than in the female. The most logical method of treatment was by neutralization of the effects of gravity on the circulation of the dependent extremity. The treatment must be simple, not too time-consuming, ambulatory, and not painful or productive of great inconvenience to the patient. It must not involve any hospitalization, it must as far as possible be permanent in its effects, and it must be cheap. The kind of treatment which he prescribed cost one shilling a week, and at St. Mary's clinic on a recent morning, out of twenty-three men whom he saw undergoing treatment, twenty-two were in full work. The principle of the treatment was support to the limb to neutralize vascular, lymphatic, and tissue fluid engorgement. The support he used was an adhesive plaster of an elastic type, applied directly to the skin. It required 6 yards of a 3 in. bandage. If varicose veins were the cause of the ulcer they were injected as they rose through the oedema expelled by the bandage. When the ulcer was healed, each case was reviewed as to the necessity of a permanent support. For some cases of "white leg" a permanent support was as necessary as a truss for hernia. Mr. Wright showed a cinematograph film demonstrating the technique of the treatment, including his method of skin grafting. He mentioned that the oldest ulcer he had treated by this method had dated back to 1877. The drawback of the treatment was the occasional development of eczema. The bandage and the injection technique were carefully shown on the screen. Into the superficial veins he injected sodium morrhuate, which could be turned into a froth.

Sir ALMROTH WRIGHT considered that Mr. Wright had succeeded in a great humanitarian achievement. His own opinion was that these cases had to be looked at from the point of view of bacterial disease. Ordinary tissue might be regarded as resembling a very close meshwork, and if a micro-organism got between the meshes it was picked up by a white blood corpuscle. But when the fluid increased in the tissues, and the lacunae became large, the micro-organism could not be dealt with in that way, and the white blood corpuscle, emerging from the capillary, was in an unfavourable fluid environ-

ment. Therefore the oedematous tissue was a suitable focus for the development of micro-organisms, and that was the condition which existed in varicose ulcer. Every kind of micro-organism was found, and the question was how an organism which ordinarily would not grow in serum became so changed that it would do so. He suggested that the white blood corpuscles, coming out to trace the microbes, found themselves in unfavourable conditions, and degenerated, giving up trypsin. The trypsin overcame the antitryptic power of the blood, which was the only thing that kept these microbes from growing in it. This bacterial condition was not very amenable to vaccination. If one wanted to prevent suppuration of a blister, one pricked the blister and let out the fluid. The treatment of these infections was to let the fluid out. In the war he found that to put a salt solution into the wounds drew out the fluid, but that was very irritating to the ulcer. Another method was by the use of a " lymph leech "—that is, a test tube in which a vacuum was made and fluid drawn out—but that method was not to be recommended for varicose ulcers. The only method which seemed practicable was the one, expounded by Mr. Wright, of using strong pressure over the whole area, converting an oedematous tissue, which was a possible soil for microbes, into a tissue in which they could not grow. A striking part of Mr. Wright's technique was the making of skin grafts. Grafts had been made with the greatest care, but large numbers of them had been found to die, probably because, with the white blood corpuscles disintegrating on the surface of the wounds, and the liberation of trypsin, the tender roots of the grafts could get no hold. If the grafts, however, were pressed in, they got into a region definitely antitryptic, and that had a great bearing on the success of the result. What he did not understand was why the cases did not break down again after the skin grafting, with the patient still going about in the upright position.

Sir ERNEST GRAHAM-LITTLE said that the treatment of this troublesome condition by Mr. Wright at St. Mary's Hospital had been a revelation to him. These ulcerations were a reproach in every dermatological department, but now the patient with varicose ulcer need not be kept from work, nor need the expenditure on treatment be considerable. Mr. Wright had converted a vicious circle into a one-way street. He questioned any implication that this was a superficial infection. A superficial infection was quickly subjugated by surface antiseptics, but these did not avail with varicose ulcers. In the correspondence columns of the *British Medical Journal* the statement had been made that this was the revival of an old method ; if so, the method had fallen into disuse, and Mr. Wright was entitled to every credit for re-establishing it in such a way as to constitute a revolution in treatment such as he himself had witnessed in scarcely any other branch of medicine.

Mr. TURNER WARWICK spoke on the mechanics of venous return, and showed slides from which he argued that this was not a gravitational mechanism, as Mr. Wright supposed, but a backward and forward movement through the perforating veins, so that he still preferred the term " varicose ulceration." Mr. D. H. PATEY had found elastic compression result in the healing of ulcers which had failed to respond to other technique, but he thought equally good results might be obtained more cheaply by painting the whole of the leg, including the ulcer, with Unna's paste, and then applying a crêpe bandage. This had the advantage that sweat was not retained, and there was not the same tendency to dermatitis. Dr. H. G. ADAMSON recounted the history of early treatment of this kind, as given in his letter in the *British Medical Journal* of February 14th (p. 284), noting the work of Richard Wiseman, Michael Underwood, Thomas Whately, and Thomas Hunt. Mr. J. E. H. ROBERTS thought that credit was due to Mr. Wright and to any man who introduced a method—whether or not it had been introduced before—in such a way that it came into general practice. Although the method of compression was an old one, it had virtually died out until Mr. Wright reintroduced it, with improvements in technique, combined with the modern treatment of injecting veins and skin grafting. Mr. H. W. S. WRIGHT pointed out the importance of a continuance of skilled care in all these cases.

Mr. DICKSON WRIGHT, in reply, said that about 75 per cent. of the patients provided the veins had been injected and the oedema reduced, could be sent away by the surgeon with a fairly easy mind. He instructed them to discard shoes, if possible, and to wear boots, to put a piece of sticking plaster over any graze, and to return to the clinic on any sign of recurrence. The other 25 per cent. were old fracture or typhoid cases and the like—people who were never safe from ulceration. But why leave them ulcerated because the ulcer was going to recur? It was easier to look after them and keep them well than to let them relapse and then attempt to cure the condition. He defended the term " gravitational ulcer " ; " varicose ulcer " led one to suppose it due to varicose veins, which was not always the case. The average time for removal of these bandages at St. Mary's Hospital was once every three weeks.

PROTEIN CONTENT OF THE PLASMA

A meeting of the Section of Medicine of the Royal Society of Medicine was held on February 24th, with Dr. R. A. YOUNG in the chair, when a discussion on the practical significance of the protein content of the blood plasma was opened by Professor I. SNAPPER of Amsterdam.

For years, Professor Snapper said, we had been trying to pump chemical substances into the blood of patients as a therapeutic measure, but it was probable that the physical properties of the blood were far more important than its chemical properties. In the study of immunology it was thought at first that antitoxin was a chemical substance ; now it was believed to be the result of a change in the physico-chemical properties of the blood plasma. Hypoproteinaemia, to take another example, had been held responsible for the appearance of oedema, but in his opinion a diminution of protein could not possibly be the sole cause. The chief subject of his address was the sedimentation rate of the red blood cells ; the older physicians had known that the blood of pneumonia patients showed more rapid sedimentation than that of the normal person, and had based their prognosis on this factor. If 2 c.cm. of normal blood were mixed with 0.5 c.cm. of sodium citrate, and part of the mixture was drawn into a 1 c.cm. pipette suitably calibrated, it was found that at the end of one hour 6 to 12 mm. of plasma had become visible at the top ; with a pneumonia patient the sedimentation rate was so greatly increased that as much as 100 mm. of plasma might be visible at the end of an hour. In other serious organic diseases the same thing occurred, and the practical value of an increase in the sedimentation rate lay in the indication it gave of some grave organic disorder. The responsibility for the acceleration lay with the plasma, not with the red corpuscles, for if the cells of a pneumonia patient were separated by centrifugalization, and mixed with plasma from a normal person, the rate of sedimentation was not increased ; whereas if normal blood cells were mixed with pneumonic plasma the rate was accelerated. The substances in the plasma responsible for the change, as could be shown in various ways, were fibrinogen and globulin. Blood from a pneumonia patient, for example,

which had been defibrinated by shaking with glass beads, or by stirring with rods, no longer showed an increased sedimentation rate. It might be argued that the stirring had altered the blood in other ways, but it could be demonstrated that where the globulin content of different samples of blood was normal the sedimentation rate varied directly with the fibrinogen content. But in other cases it had been found that the sedimentation rate was increased, although the fibrinogen content was normal; in these the globulin content was raised. A third factor influencing the rate was the cell content of the blood; in anaemias the reduced viscosity of the blood led to a more rapid sedimentation. Fibrinogen and globulin were responsible for the rate at which the blood cells were coagulated into masses, but once these masses were formed the sedimentation rate depended on the viscosity of the blood, and hence on the anaemia. Fibrinogen was formed in the liver, but in cirrhosis or chronic venous congestion of the liver the sedimentation rate was increased, because the globulin content of the blood was raised. Why, he asked, should an increase of fibrinogen or globulin give rise to an increased sedimentation rate? It used to be thought that the negative charge on the red blood cells repelled them from each other, and that when this charge was reduced they agglutinated. This argument could not be maintained. It was easy to diminish the sedimentation rate *in vitro*; the addition of novasurol to blood with a high sedimentation rate led to a marked diminution. Professor Snapper said that he had tried other diuretic substances with variable effects; euphyllin and caffeine citrate had not reduced the rate, but diuretin had caused a great reduction, and so had salicylic acid, although benzoic acid had not. But the negative charge on the corpuscles, the fibrinogen content, and the viscosity were all equally unaffected by the addition of salicylate, and the explanation appeared to be that salicylates had an influence on the stability and lability of the plasma proteins. The rate of sedimentation was only a function of the stability and lability of these proteins, and the whole phenomenon was a physical rather than a chemical one.

Dr. W. PAYNE said that he had been working on the sedimentation rates in acute rheumatism in children during the past year. He had found that the rate ran parallel with the clinical findings, and had usually returned to normal by the time the physician in charge had said the child was ready to get up. In cases that were going to relapse the sedimentation rate remained high, and in several cases of sore throat due to haemolytic streptococci the sedimentation rate had gradually increased after apparent recovery, and a relapse had supervened. The use of salicylate appeared to mask symptoms in some cases; he described a case in which the child had apparently returned to normal, but on withdrawal of salicylates the symptoms returned; the sedimentation rate had remained high throughout.

Dr. J. FORESTIER spoke of the value of the sedimentation test in chronic arthritis. In osteo-arthritis and so-called fibrositis the sedimentation rate was normal, but in rheumatoid arthritis it was markedly raised. He had found it to be the best test to estimate the value of treatment, and a patient with rheumatoid arthritis could not be said to be cured until the sedimentation rate was normal. Dr. GEOFFREY MARSHALL had found that the sedimentation rate was increased in pulmonary tuberculosis when the inflammation was extending, and was reduced during healing.

The CHAIRMAN said he had used the sedimentation test as a routine in chest cases for the past four or five years. An increased rate was not valuable from the point of view of diagnosis, because it was found in so many conditions, but it had impressed him as being valuable in prognosis and in suggesting treatment. He wished there was more uniformity in the manner of recording the rate.

In replying, Professor SNAPPER said that although it was true that in certain cases the sedimentation rate ran parallel to the course of the disease, a normal sedimentation rate did not necessarily exclude severe disease in every case; in the late stages of degeneration of the liver, for example, less fibrinogen was formed, and the rate fell. It should not be regarded, therefore, as a true indication of improvement or the reverse. The method he employed was that of Westergren. His reason for not accepting hypoproteinaemia as the sole factor producing oedema required explanation. We were taught that there must be an equilibrium between the pressure inside the capillaries and the pressure outside, which was maintained by osmosis. But the proteins could not permeate the vessel walls, and therefore they exerted a small but constant pressure, which, until lately, we had been taught to neglect. As there was a hydrostatic pressure of 35 cm. of water from the heart forcing fluid out of the vessels, the proteins probably played an important part in preserving the balance. A reduction of protein might therefore be expected to lead to an escape of fluid into the tissues, such as that which occurred in the hypoproteinaemia present in nephrosis. But in all cachectic diseases the albumin and globulin of the blood were decreased—in such divergent conditions as lymphogranuloma, pulmonary tuberculosis, degeneration of the heart, and tumour of the lung; and oedema might, of course, be present in any of these diseases. Nevertheless, it was always possible to find some cases with a low colloid osmotic pressure and no oedema. Moreover, if blood were repeatedly withdrawn from a dog, defibrinated, and reinjected, until the colloid osmotic pressure were greatly reduced, no oedema would develop unless sodium chloride was given; the gross oedema which arose then disappeared rapidly when diuresis was produced, showing that hypoproteinaemia alone was insufficient to cause oedema.

TREATMENT OF GLANDULAR DEFICIENCIES

At a meeting of the Chelsea Clinical Society on February 17th, with Dr. F. J. MCCANN in the chair, a discussion on the treatment of glandular deficiencies was opened by Dr. W. LANGDON BROWN.

Dr. Langdon Brown said that the practitioner was constantly being torn between the confident claims of manufacturers and the conservatism of the laboratory worker. Enterprising firms had made the diagnosis and treatment of glandular diseases the simplest matter in the world for the jaded practitioner, but the laboratory worker demanded that the gland in question should be one which formed an internal secretion, that an active principle of the secretion could be extracted, and that a method of administration of the extract should be found which would admit of its utilization by the body. Herein the laboratory worker was right, but he was wrong in being extremely sceptical of any other evidence. Myxoedema and many other conditions were all discovered at the bedside, and associated with a glandular disturbance before the laboratory had any idea of the functions of the gland in question. There was no reason, therefore, to apologize for using empirical methods. Empiricism had often won therapeutic success which had had to wait long for scientific explanation. Endocrine therapy won its first easy triumphs with thyroid extract, and for some time it was not realized that the conditions obtaining there were rather exceptional. The thyroid gland contained a considerable reservoir of secretion, and the extract could be readily assimilated by the alimentary tract. Organotherapy had not kept pace with endocrinology, and this was just as well, for if all the extracts given had been potent much harm would have been done. Advance was

being made along certain definite lines in addition to the empirical one—namely, (1) the isolation of new hormones; (2) the introduction of methods of physiological standardization, such as the lowering of blood sugar for insulin, and the estimation of the calcium content of the blood for parathormone; (3) the exploration of new routes for administration, the most successful being the giving of pituitrin by the nasal route; (4) the use of synthetic drugs, which, while having similar pharmacological actions to hormones, were capable of oral administration; (5) the use of other drugs or physical methods to affect the endocrine glands, iodine medication in thyroid disorders being the outstanding example. Dr. Langdon Brown then went on to consider the application of this treatment to certain glandular deficiencies. On hypothyroidism he called attention to three points: (1) that minor degrees of hypothyroidism were still frequently overlooked; (2) that it was advisable to start with a small dose and push up gradually; (3) that cases of mongolism or hypopituitarism were still sometimes mistaken for hyperthyroidism, and although thyroid medication might help such patients, the results naturally were not nearly so good. By far the commonest type of pituitary deficiency in his experience was Fröhlich's syndrome of obesity and sexual hypoplasia. In dealing with cases in which there was a history of rather premature development followed by a check, pituitary and thyroid combined was the best treatment. In a discussion of gonadal hormones, he mentioned that he had utilized the luteal hormone successfully for checking prolonged lactation, for relieving the pituitary headache which afflicted some women on putting the infant to the breast, and in some cases of habitual abortion. The luteal hormone was essential for the maintenance of hypertrophical uterine mucosa in which the embryo could find a nest. After dealing at some length with oestrin, and giving the conclusions of Parkes's very careful monograph on the internal secretions of the ovary, the speaker touched slightly on adrenaline deficiencies, and concluded with a few remarks on parathyroid extract, saying that it was not at first realized that parathormone raised the blood calcium at the expense of the bones; it was therefore strongly contraindicated in rarefying diseases of the skeleton. Brilliant as were the effects of parathormone in acute tetany, it was much less satisfactory in the chronic type, where irradiated ergosterol and calcium salts, especially if aided by hydrochloric acid, might be very helpful. As to the position of insulin, this was now undisputed. Sometimes in children it acted so quickly that it was difficult to prevent the hypoglycaemic reaction. Graham had utilized the well-known antagonism between insulin and pituitrin by giving, for example, two units of the latter to twenty of the former, and so delaying the rate of fall in the blood sugar.

Dr. HAROLD PRITCHARD said that he had treated cases exhibiting Fröhlich's syndrome by giving a mixed preparation of thyroid and pituitrin by the mouth; the cases were later treated by giving thyroid by the mouth and pituitary extract under the skin, with improved results. He also raised the point as to whether a blood sugar curve would be of any value in estimating the basal metabolic rate, and whether there was any evidence that immunity against bacterial infections could be raised by increasing the hormone content of the blood.

Dr. CAMPBELL MCCLURE said that it was the clinician's duty to make increasing trial of organotherapy. The clinical results came first as a rule, and laboratory confirmation followed. The surprisingly successful results attributed to organotherapy by many practitioners might be due to the fact that many of the cases dealt with were highly suggestible, and that the practitioner was apt to attribute the good results to some preparation or other instead of to his own personality. He thought there was no doubt as to the activity of parathyroid given by the mouth. The depression following overdosage with pituitary by the mouth showed that in this case also absorption of an active substance took place.

Dr. PHILIP ELLMAN, speaking of the parathyroid gland, said that some years ago, before using any extract of parathyroid, he had a number of preparations carefully examined, and whilst several were composed of thymus and lymph gland tissue, only one contained a true extract of parathyroid. However, Collip's parathormone was now on the market, and was a most valuable preparation. Combined with preparations of calcium in suitable cases, especially gluconate of calcium, the treatment was such that calcium metabolism could be influenced as surely as sugar metabolism was influenced by insulin. He went on to refer to the value to be derived from an estimation of the calcium content of the blood in disease and as a means of control of therapeutic measures concerning calcium metabolism. Estimations he had made showed that the blood calcium in pulmonary tuberculosis was almost always within the normal limits of 9 to 11 mg. per 100 c.cm. of blood; but where, in active cases, the blood calcium was within minimal normal limits it could be raised by a combination of calcium and parathyroid therapy to maximum normal limits, with corresponding improvement in the pulmonary and general conditions.

Mr. C. HAMBLEN THOMAS instanced cases of middle-ear deafness, head noises, and frontal headache which had been benefited by treatment for endocrine disturbance. Mr. PHILIP FRANKLIN said that in certain cases of dysmenorrhoea the effect of desiccated whole gland or posterior pituitary substance was most startling, if one had sufficient experience to be able to select one's cases and choose the psychological moment. This latter was of vital importance; to know what case to choose and how to use the appropriate therapy was to have success, for the specificity of endocrines was amazing, and slipshod methods were of no use whatever.

Other speakers included Dr. MONTAGUE SMITH, Dr. DICKSON, and the PRESIDENT, the last-named referring to the value of organotherapy as applied to gynaecological conditions, on which, he said, he would have more remarks to make at a subsequent meeting.

UNUSUAL TUMOURS

The Section of Pathology of the Royal Academy of Medicine in Ireland met on January 23rd, the president, Dr. J. LAIT, in the chair.

Dr. L. G. GUNN read a note on a case of myelomatosis. The patient was a woman, aged 63, who had a history of nephritis for thirteen years. She fell, hitting her head against a fender, and owing to severe headache sought hospital treatment. In hospital the urine was found to contain Bence-Jones albumose. An *x*-ray examination showed several clear spaces in the bones. The patient died shortly after admission, and at the post-mortem myelomatosis was found. Dr. J. T. WIGHAM said that a discoloured swelling over the patient's eye, which might have been put down to trauma, proved to be a tumour. Microscopical sections showed numerous plasma cells. The tibia and fibula were removed, and longitudinal sections showed an extensive cystic condition. Dr. Wigham drew attention to the fact that the tumours had developed as separate nodules. All the bones of the body were myelomatous. The gall-bladder was full of gall-stones. The PRESIDENT said that only five of these cases had been reported in Ireland, and Bence-Jones proteinuria was present in all of them; it was found in less than 50 per cent. of the cases reported in Great Britain. In one of the reported cases 28 per cent. of myelocytes and plasma

cells were present in the blood. He regarded these tumours as of blood-forming tissue origin.

Sir WILLIAM WHEELER read a note on a case of tumour of the neck, the diagnosis of which presented difficulty. (See figure.) The patient was aged 26, and there was a history of about fifteen years. Clinically the growth was non-malignant; it was freely movable and painless, and extended from the lower lobe of the ear to the sterno-clavicular joint on the left side. It was not translucent with a Cameron light. A limited area of calcification could be seen in the *x*-ray photographs. An exploratory puncture resulted in the withdrawal of blood only. The tumour was soft and solid, giving, on palpation, the impression of a lipomatous mass. Obviously it did not spring from the parotid or thyroid glands. It had no resemblance to a tumour of the parotid gland. The provisional diagnosis, by a process of exclusion, was that the growth belonged to the lymphangiomatous group. At the operation the tumour was found to be enclosed in a thin vascular capsule In consistency and vascularity it resembled a goitre. The lower pole of the tumour lay in close relationship to the confluence of big veins above the clavicle and, higher up, to the deep vessels of the neck. It was not infiltrating or adherent. The operation was not unduly difficult, nor was there much haemorrhage, but the day following operation the heart commenced to fibrillate, and the man died suddenly. A complete post-mortem examination was not permitted.

Malignant endothelioma (?) of the neck. Clinically non-malignant.

Dr. J. LAIT, in demonstrating the specimen, said the tumour was heart-shaped, measured 6½ by 4 inches in its greatest diameter, and when fresh weighed 16 ounces. Its anterior surface was smooth, and in part covered by a thin capsule, to which were attached a few lymph glands. The upper pole was rather lobulated. When fresh the tumour was quite soft, and almost cystic to the touch; but when fixed and sectioned it was found to be entirely solid. The cut surface was divided into irregular oval-shaped areas, and was of a homogeneous structure, with scattered areas of haemorrhage. From the macroscopical appearance there could be little doubt that the tumour originated in the cervical lymph nodes, and there was no doubt of its being malignant, probably endotheliomatous. In one section there were large polyhedral cells, with faint outline, and large vesicular nuclei, occasionally grouped together in an imperfect syncytial arrangement. In another this structure was absent, there being a marked fibrosis. In still others, large cells appeared proliferating in the follicles of the glands. It was of interest that these tumours were often preceded by a granulomatous inflammation. A section from the periphery of the tumour showed a tuberculous gland.

Dr. J. MCGRATH thought the tumour was a lymphoma. Dr. R. R. WOODS said that he had had a similar case as far as pathological findings were concerned, but clinically quite different. The patient was a man, aged 55, whom he had seen last September with a large swelling at the base of his tongue, which had been present for about two months. The swelling was so large that when the patient put out his tongue he could not breathe. A diagnosis of carcinoma was made, and deep *x*-ray treatment given. Soon after this the man coughed up blood and pus, and Dr. Woods thought that the swelling was an abscess at the base of the tongue. A specimen was taken, and the pathological report received stated that it was a carcinoma. The tumour was very friable; as a result of deep *x*-ray treatment it disappeared.

Sir WILLIAM WHEELER read a note on a case of unusual renal tumour. The patient was a man, aged 50, suffering from haematuria. There were no other signs or symptoms. The blood urea was normal. A cystogram of the bladder showed nothing abnormal. No pus or organisms were found in the urine. A renal tumour was suspected in the first instance. Cystoscopic examination was rendered very difficult owing to the presence of blood; the mucous membrane of the bladder was seen to be oedematous in the region of the trigone, and was bleeding at various points; it was therefore concluded that the haemorrhage was from the bladder. A suprapubic cystotomy was performed, and an area of bleeding mucous membrane about the size of a two-shilling piece was fulgurated until the field was dry. The patient's temperature rose to 105° F. a few days after operation. A swelling quickly appeared in the parotid gland, which was incised and found to be composed of necrotic tissue, which gave a culture of *Staphylococcus aureus*. The man died of pyaemia. The tumour found in the left kidney post mortem was probably the main source of the haematuria, but the cause of the bleeding from the bladder mucous membrane was obscure. The acute pyaemia after operation could not be explained.

Dr. W. BOXWELL and Dr. J. LEWIS, in demonstrating the specimen, said they considered the bleeding referred to by Sir William Wheeler might have been due to the papillomatous condition of the bladder. There was no evidence on section of a tumour in the bladder or the prostate, but both were riddled with abscesses. The lower pole of one kidney showed a small papillary adenocarcinoma and many abscesses. The PRESIDENT said that at first sight this tumour might be taken for a hypernephroma. He had no doubt, however, that it was a papillary carcinoma, and that the tumour originated from the kidney epithelium.

ASPECTS OF RADIUM THERAPY

The February meeting of the British Institute of Radiology was devoted to papers dealing with radium. The president (Major C. E. S. PHILLIPS) mentioned that a conservative estimate of the total amount of radium available in the world to-day was approximately 25 oz. This was based on the fact that at the end of 1928 there were 575 grams, and since then rather more than 120 grams had been produced at two mines. The Government of the United States owned 50 grams, the British Government 49, and the French Government 31.5.

Dr. ROY WARD gave a general survey of the present position with regard to the use of radium in the treatment of benign and malignant conditions. He said that in spite of the favourable results obtained with radium in inoperable and recurrent carcinoma of the breast, it was not considered justifiable as yet to advise radium treatment alone for early cases. Time would answer the question whether radium would replace surgical measures in the treatment of operable cases of mammary cancer. During the last five years a great advance had been made in the treatment of carcinoma of the cervix uteri. There was no doubt that radium therapy had increased the number of cures in this condition. In advanced cases it had done more to alleviate symptoms and prolong life than in any other group of cancers. In a large number of cases of carcinoma of the rectum, radium treatment, if given with care, controlled the haemorrhage and discharge. In epithelioma of the anus it was possible to bring about complete regression of the growth. Dealing with some non-malignant conditions in which radium therapy had proved beneficial, Dr. Ward showed photographs of two cases of Mikulicz's disease, a peculiarly

symmetrical disease of the lacrymal and salivary glands, which cleared up remarkably well under radium treatment.

In the course of the discussion, Dr. E. A. LYNHAM considered that the combination of radium and *x* rays in cancer would ultimately prove to be the method of choice. He was also of the opinion that there was a great future for pre-operative radiation. Dr. G. VILVANDRE had seen cases where, after an indifferent result with radium, *x* rays had been applied with amazing results. Radium failed where there was metastasis. At the London Hospital there were records of patients with breast cancer who had been treated by *x* rays, and were alive after more than ten years. Dr. N. S. FINZI contested a statement, made originally by Professor Regaud of Paris, that radium was of little value in columnar-celled carcinoma. He recollected several cases of this type in which the patients had remained well for periods of over five years. He considered that the treatment of *x*-ray dermatitis by radium was completely unjustifiable; after such treatment the cases were likely to develop epitheliomata. The only effective treatment was excision of the area, followed by skin grafting. In naevi it was well to give a moderate dose and to wait a very long time for the effect. The changes in naevi went on for at least a year after the original application, and if the treatment went too far there was a tendency to get white scars and subsequent formation of telangiectasis. Dr. W. M. LEVITT did not believe that the treatment of lymphosarcoma by radium in preference to *x* rays was reasonable. Radium in the form of a "bomb" might be, but radium by the interstitial method was not justifiable. Dr. MALCOLM DONALDSON said that by force of circumstances he was himself a clinician, but his heart was in the laboratory, and if real progress was to be attained it was the laboratory side that must be encouraged. He believed that the study of the Swedish school, particularly on the subject of the tumour bed, would throw a great deal of light on tumour formation.

Radium and X-Ray Service in Australia

Dr. A. BURROWS, who has acted as radium adviser to the Commonwealth of Australia, gave an account of the radium and *x*-ray cancer service there. The Federal Government has purchased 10 grams of radium, and a large centre has been established in each capital city, to which all cases of cancer are referred, and in which research work is also organized. An up-to-date cancer clinic, equipped with radium, apparatus for deep *x*-ray treatment, adequate laboratory facilities, and means of testing, has been established in Sydney, Melbourne, Adelaide, Brisbane, Perth, and Hobart. The Commonwealth radium is distributed on loan by the Government to these various centres, and agreements are signed between the Government and the local authorities providing for the care and custody of the radium. In each centre a clinical director has been appointed to have general control of radium and *x*-ray treatment, and there is also a clinical committee which meets to discuss when possible the most suitable form of treatment for each case, and, if necessary, to assign the case to the person most suited to carry out the treatment recommended. Four radium emanation depots have been formed, at Sydney, Melbourne, Brisbane, and Adelaide, the one at Melbourne being under the direct control of the Commonwealth Government. Mass treatment with four grams of radium was at first carried out at one of the centres, but it has not been found possible to continue this work, and the breaking up of the quantity was done without reluctance, because the results obtained had not been too promising. In every case it was insisted that deep *x*-ray therapy should be provided, together with radium treatment at every centre. The *x*-ray apparatus, however, has been for the most part purchased from funds locally raised. During the first year of the scheme more than 3,000 cases were treated by radium or by *x* rays.

PLASTIC SURGERY

At the February meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland, with the president, Mr. R. ATKINSON STONEY, in the chair, Mr. T. POMFRET KILNER (London) read a paper on the role of plastic surgery in the treatment of lupus vulgaris, and showed two patients on whom he had performed the operation of reconstructive rhinoplasty. After stressing the importance of co-operation between the plastic surgeon and the dermatologist, Mr. Kilner pleaded for early surgical intervention in the terminal, or healed, stage of the disease in order to remedy the unsightly deformities which resulted, particularly destruction of the nose and cicatricial ectropion of the eyelid. Plastic operations, suitably planned, could transform disfigured patients into normal-looking individuals, capable of finding work. The speaker outlined the method of repair by Thiersch grafting employed in cicatricial ectropion, and described the technique of reconstructive rhinoplasty by a pedunculated forehead flap. Replying to questions, Mr. Kilner said that *x*-ray burns in the neck were very difficult to deal with. He considered that the essential treatment was to remove all the burnt area, otherwise the neurofibrosis which produced pain could not be got rid of. Tube pedicle grafts should not be done in very young children. A considerable amount of judgement was required in deciding the length of a tube pedicle in relation to its width. He never made them more than six inches long, or less than two and a half inches wide.

ORGANIC NERVOUS DISEASE

At a meeting of the Brighton and Sussex Medico-Chirurgical Society, held on February 5th, with the President, Mr. H. N. FLETCHER, in the chair, Dr. W. J. ADIE gave an address entitled, "Early symptoms of common organic nervous diseases." A majority of the patients who came complaining of their "nerves" would, he said, be found on investigation to be suffering from one of the minor disorders of the mind, a psychoneurosis. But grave disorder of the mind, disorder of function not necessarily of mental origin, such as paroxysmal tachycardia or migraine, grave organic disease in parts outside the nervous system, or organic nervous disease itself might be the cause. Further, the clue to the pathological nature of organic nervous disease was often discovered outside the nervous system; hence a careful general examination was necessary in every case. The distinction between functional and organic nervous disease could usually be made with the aid of the cardinal tests—pupils, discs, abdominal, knee, ankle, and plantar reflexes. In doubtful cases, if these tests showed nothing abnormal, organic nervous disease was unlikely, apart from early paralysis agitans and the Parkinsonian syndrome. Unfortunately, few but expert neurologists could make these simple tests efficiently, and assess the findings accurately. Young graduates left the hospitals with knowledge much of which was ephemeral, but with little skill. The differential diagnosis of organic nervous disease was not easy, though it was not as difficult as it was made to appear to be by teachers who demonstrated rare and advanced cases, but gave no sense of proportion. Few organic diseases of the central nervous system were common. Disseminated sclerosis, syphilis, and cerebral tumour were easily first. The numbers seen at Queen's Square in a year ran into hundreds. Cases of paralysis, subacute combined degeneration, and progressive muscular atrophy were counted in tens. Of the rest, apart from the various sequels of epidemic encephalitis, the numbers were very small. Dr. Adie then described in detail the early symptoms of tabes, disseminated sclerosis, subacute combined degeneration, and paralysis agitans, and contrasted these with the symptoms in advanced cases which formed the basis of the classical descriptions.

Reviews

PHYSIOLOGY OF BACTERIA

The treatise entitled *Physiology and Biochemistry of Bacteria*,[1] by Professor R. E. BUCHANAN and Professor ELLIS I. FULMER of the Iowa State College, comprises three volumes, the first of which has been reviewed in this *Journal* (1928, ii, 1182).

Volume ii is devoted to a consideration of the effects of environment on micro-organisms and, although its appeal will be mainly to those who study bacteriology as a science, there is much that is of practical significance to applied bacteriology. The volume is divided into three sections. The first—Section A—comprises a consideration of rates of reaction, the problem of their determination and comparison, and such questions as rate curves, survivor curves, and death curves. Section B is devoted to the effect of physical environment, and the first chapter, which deals with the effect of temperature, has much to say of importance in the industrial handling of foodstuffs, more particularly the canning and milk industries. Chapter VII commences with a brief discussion of electro-magnetic waves and emanations, and includes a useful table of the former. In discussing the effect of ultra-violet rays on enzymes and bacteria the authors do not consider the possible application of this as a means of distinguishing between living and non-living agents. The work of S. L. Baker would appear to indicate that this is a promising line of approach to the vexed question of the nature of filterable viruses. This section concludes with a chapter on the effect of various physical environments such as osmotic pressure, surface tension, and high-frequency sound waves. The remainder of the volume is occupied with a consideration of the effect of chemical environment on micro-organisms, and the opening chapter is concerned with a general discussion of the question and disinfection. Following this is a chapter on the effect of inorganic compounds and their ions. Physiological saline, so-called, is still much used in bacteriology, and is regarded by many as not harmful to bacteria. But, as Falk has pointed out, this tradition has been borrowed from vertebrate physiology and its application to bacteriology looked upon as sound, though there is evidence that such solutions produce unwonted effects which, often overlooked, are significant. There is much in this chapter of practical interest to the bacteriologist, though the introduction of tissue culture, particularly in work on filterable viruses, has inculcated saner views as to what constitutes a "physiological saline" in bacteriological work. The two concluding chapters deal with organic compounds, nitrogenous and non-nitrogenous, both subjects of vast importance.

Volume iii treats of the changes produced by micro-organisms on their environment, and is divided into two sections. The first considers the interrelations between microbes—symbiosis, commensalism, and antibiosis. It is rather surprising that under the last heading there is no discussion of the phenomenon of bacteriophagy. True, opinion is divided on the question whether the bacteriophage is a living entity or an enzyme-like agent; nevertheless we think that this would have been a more appropriate place for a consideration of this interesting phenomenon, rather than in the next section with the enzymes. The other section of this volume (which by the way is Section E in the List of Contents and Section B in the text) opens with a chapter on the agents responsible for chemical change—that is, the enzymes of micro-organisms. In the following chapters the changes wrought by these enzymes on inorganic compounds, non-nitrogenous carbon compounds, and nitrogenous organic compounds are passed in review.

The authors' task has been an extremely difficult one, for much of the territory that they cover is shifting sand. An attempt to write on a subject which is still in the unformed stage of infancy not seldom degenerates into a mere recital of researches, often conflicting, and the result is an account lacking in sequence and clarity. We feel that these volumes, though a remarkable testimony to the authors' knowledge of the literature—there are some 250 pages of references—will be of little service to those who are desirous of approaching the subject of the biochemistry of bacteria. As books of reference for those already versed in the subject, however, they will no doubt prove most useful.

[1] *Physiology and Biochemistry of Bacteria*. Vols. ii and iii. By R. E. Buchanan, Ph.D., and Ellis I. Fulmer, Ph.D. London: Baillière, Tindall and Cox. 1930. (Vol. ii, pp. xvii + 709; 57 figures. Vol. iii, pp. xv + 575; 2 figures. Each volume 34s. net.)

THE NATURE OF LIFE

It will probably be admitted, or, at all events, it will probably be found, that the two most momentous fields of work in modern biology are those of the Russian physiologist Pavlov and his co-workers on conditioned reflexes, and of Thomas Hunt Morgan and his compeers on the methods of hereditary transmission. The biological and philosophical consequences and implications of these researches are likely to prove not less revolutionary than those which, in the sphere of physics, have resulted, or are now emerging, from the theory of relativity and from the conception of the structure of the atom. A remarkable and intensely interesting book discussing these biological and philosophical consequences is *The Nature of Living Matter*,[2] by LANCELOT HOGBEN, professor of social biology in the University of London. The book is even of somewhat wider scope than that indicated. It is the expansion and outcome of the author's contribution to a symposium on the nature of life, arranged by the officers of the Physiological Section of the British Association in the summer of 1929, and a criticism of the philosophical views of General Smuts and Professor J. S. Haldane, two of the other contributors to the same symposium, who have already set out their ideas in book form. It constitutes a review of the progress of modern biology in its philosophic bearings, and claims that, although so far the physicists have assumed the leading part in the rekindled interest in the relation of science to common sense on the one hand, and the relation of science to moral philosophy on the other, it is essential that the contribution of contemporary biology to such a discussion should be taken into consideration before any assured outcome can be seen or predicted.

Professor Hogben pursues his theme under three main headings: "Vitalism and mechanism," "Darwinism and the atomistic interpretation of inheritance," and "Holism and the publicist standpoint in philosophy." The actual matters dealt with, or the aspects of the subject considered, differ distinctly in these three divisions; but the uniting thought or thesis which connects them into one whole is kept prominent throughout. In the first section it is contended that the methods of experimental biology are essentially the same as those of experimental physics or chemistry, and that the method of inquiry applicable to one aspect of the properties of living matter is not of a different kind from that employed in dealing with the remainder. The mechanization of conscious behaviour and the atomistic view of parenthood are emancipating biology from its mystical interpretations, just as the other branches of science have, though with

[2] *The Nature of Living Matter*. By Lancelot Hogben. London: Kegan Paul, Trench, Trubner and Co., Ltd. 1930. (Pp. ix + 316. 15s. net.)

vestiges still remaining, been freed from somewhat similar notions. In a summary of his second section Professor Hogben says:

"The failure to recognize that biology no less than physics is an ethically neutral science is a heritage of the evolutionary controversy. The ethical concept of progress became entangled in the evolutionary idea. Experimental biology in this generation has undertaken the task of reducing the problems of organic evolution to an exact science. This must necessitate a re-examination of many traditional biological concepts and influences which have been extracted from an earlier phase of the evolutionary doctrine."

He proceeds to this examination of the method of evolution, and, among other things, defines the restricted sphere of natural selection, and of the struggle for life and the survival of the fittest. In his third section the author develops the concept of a public world of science which is significant for discussion or discourse as contrasted with, or distinct from, the private world of individual belief with regard to the problems of existence.

"This antinomy does not necessarily reside in the system of nature. It arises because our curiosity exceeds our information. Up to a certain point we succeed in pooling our experiences by the method of science. In so doing we construct the public world." But "man is pre-eminently interested in himself. So long as science cannot satisfy that curiosity his private and personal values assume a greater importance than the academic hypotheses of science. At every stage in the advance of scientific knowledge a new system has arisen to conserve some fragments from the wreckage of supernatural beliefs."

This line of thought is admirably and lucidly developed. Professor Hogben truly says that "there is no issue which provides more scope for vague, barren, and undisciplined discussion" than the nature of life. His own discussion of that problem, embodied in this volume, deserves epithets the opposite of these. It is clear, suggestive, forceful, and purposive, based upon a fullness of knowledge, and enlivened with delightful touches of humour.

PHYSIO-PATHOLOGY OF SLEEP

Professor ALBERTO SALMON in his book on the Physiopathology of Sleep[3] refers to the fact that the present treatment of insomnia consists almost exclusively in the administration of hypnotics; these, however, produce merely a toxic sleep, fail to effect a cure, and require to be continually repeated. The means of curing the disorders of sleep will, he maintains, be forthcoming only when an intimate knowledge, not only of the causes producing such disorders, but also of the physiology of sleep, has been acquired. Although the latter subject is surrounded by obscurities, a number of significant facts are already known, and, in the opinion of the author, they are sufficient to justify an attempt to propound a consistent theory.

It has been shown experimentally that induced insomnia causes an intense chromatolysis in the cells of the cerebral cortex, especially of the frontal lobe, and that a few hours of sleep bring about a complete restoration of the chromatin content of the cells. This suggests that some form of secretory activity is involved in the induction of sleep—that sleep coincides with a process of internal secretion of the cells of the cortex, determining the periodical suspension of their activity. A periodical functional activity of this kind presupposes a regulating mechanism, and many clinical and experimental observations point to the diencephalon or infundibulum as being the seat of a regulating sleep-centre. Thus Demole was able to produce intense and prolonged somnolence in animals by injecting calcium salts into the region of the infundibulum, and many clinical facts derived from cases with pathological lesions in the same region support the view that such a centre exists. There appears to be still more abundant evidence that the pituitary body plays an important part in the mechanism of sleep. Batelli and Jauffret, for example, have shown that an intense and prolonged somnolence can be produced in animals by injecting pituitrin into the cerebral ventricles; and the clinical facts bearing on this point are also very numerous. One need only refer to Cushing's conclusion, based on the observation of 500 cases of pituitary disease, that insomnia should be counted as one of the definite symptoms of lesions of that gland; and to the fact that a syndrome (that of Simmonds), comprising pituitary cachexia and somnolence, is now fully recognized.

The pituitary theory of sleep was first proposed by Professor Salmon in 1905 and more fully elaborated in 1910, and his account of the correlation of the function of the sleep-centre, the pituitary body, and the chromatolysis of the cortical cells, forms the most interesting part of his book. Other matters are, however, discussed with equal fullness, and the work may be regarded as a complete textbook on the subject of sleep and its disorders.

CUTANEOUS LEISHMANIASIS

Cutaneous leishmaniasis is a disease not often seen in the West, and one which consequently has not received much study by European dermatologists. It is endemic—and sometimes epidemic—in Greece and other Mediterranean countries, and considerable contributions to our knowledge have come from these countries. A recent volume,[4] by the distinguished Greek dermatologist Dr. HIGOUMENAKIS, is therefore of some interest. After a historical introduction, the author gives a careful account of the morphology and biology of the parasite. He then considers methods of transmission, and shows that this is by contact as well as by flies and other insects. The disease can be experimentally inoculated into monkeys, dogs, and mice. The next chapter studies the pathological anatomy of the lesion and the blood changes. The remaining chapters deal with the typical and atypical disease in man and its differential diagnosis from other skin conditions. After a short chapter on prophylaxis, the author goes on to study the treatment of the disease. He considers that the most satisfactory method of treatment is diathermo-coagulation, the technique for which he describes. This chapter contains a description of thirty recent cases observed by him, and treated by this method. The book concludes with an extensive bibliography. It is illustrated with photomicrographs and clinical photographs, and the writing is clear. This is an important contribution to our knowledge of cutaneous leishmaniasis which will prove of much value to those resident in lands where the disease is found.

A DICTIONARY OF DENTAL SURGERY

In the hope of providing the student and the practitioner of dental surgery with a ready means of refreshing his memory, and with a reference book in which will be found many practical details of use in the surgery, Mr. FLEMING MCASH has compiled *A Dictionary of Dental Diseases and Treatment.*[5] Such a method of dealing with a scientific subject does not lend itself to exhaustive discussion of any one point, and the author has wisely kept well within his self-imposed limitations. Opening the book at random

[4] *Le Bouton d'Orient (Leishmaniose Cutanée) et son Traitement Moderne.* Par Georges Higoumenakis. Avec préface du Dr. Milian. Paris: Masson et Cie. 1930. (Pp. vi + 150; illustrated. 25 fr.)

[5] *A Dictionary of Dental Diseases and Treatment.* By J. Fleming McAsh, L.D.S.Ed., L.R.C.P.E., L.R.C.S.E., L.R.F.P.S.Glas. The Edinburgh Medical Series. London: A. and C. Black, Ltd. 1930. (Pp. v + 285. 7s. 6d.)

we came on "bleaching of teeth" and found nearly a dozen methods described—shortly, but sufficiently to recall the chemistry and the technique learned in student days. The method, however, has its drawbacks; brevity may be carried too far—for example, we should like to know how long an arsenic "dressing" may be left *in situ* on an exposed pulp; and the alphabetical arrangement of the subject-matter destroys all continuity of thought by the juxtaposition of such incongruities as artificial respiration and attrition. The author, indeed, has been a victim of his own plan. Under "affections of the third mandibular molar," and under "mandibular third molar, affections of" we find practically the same article; and in the index there is no mention of the homely term "wisdom tooth." (Does not the need for an index rather discount the value of an alphabetical arrangement?) The dictionary closes with weights and measures, prescription writing, dosage, incompatibles, synonyms,—all under "W," but making a chapter for which the author will earn the thanks of all his readers. We think this book may be trusted to serve its avowed purpose: it will bring back to memory half-forgotten things, and it is full of practical details any one of which may be exactly what the practitioner is seeking.

NOTES ON BOOKS

When a new textbook of surgery reaches a second edition in these days of innumerable textbooks, it may be assumed that it has met a certain demand. And yet it must be admitted that any attempt to "crystallize and condense" into 370 small pages "the more important principles of surgery for the benefit of the student" is a matter fraught with extreme difficulty. Dogmatism is inevitable, and with this come fallacy and half truths; it cannot be claimed that the author of *A Shorter Surgery*[6] has, any more than others who attempt a similar task, avoided this defect. In order to help as many readers as possible material suitable for higher examinations is included in small type—a tempting solution no doubt, but apt to upset the balanced treatment of the various subjects. In any case, such a book should be free from obvious inaccuracies—for example, that the external malleolus is broken in Pott's fracture, and that Cooper's ligament is a fascia covering the pectineus origin; and it should not employ "diverticulae" and "sequestrae" as plurals. In short, the book deals not so much with principles as with abbreviations of facts, and sometimes it does this in a misleading way. It may, however, prove of distinct value to the final student in giving him a change from the standard textbook on which he has got "stale," and allowing him to see things from a different angle. He will find it eminently readable, the illustrations, with one or two exceptions, very good indeed, and the index reasonably comprehensive.

The third volume of the fortieth series of *International Clinics*[7] includes, among many contributions, a series of instructive papers emanating from the Fifth Avenue Hospital of New York City, the University of California Medical School, and the Heckscher Institute for Child Health of New York City. Special mention may be made of the following: the surgical consideration of acute lymphadenitis, by Dr. Charles W. Lester; treatment of carbuncles and cellulitis about the neck and face, by Dr. Kingsley Roberts; factitial proctitis, a justifiable lesion observed in patients following irradiation, by Dr. Louis A. Buie and George E. Malmgren; drug addiction, by Dr. Alexander Lambert; a symposium on epilepsy, by Drs. Temple Fay, Eugen P. Pendergrass, N. W. Winkelman, William G. Spiller, and A. E. Bauer; forty-five years of personal experience with headache, by Dr. James J. Walsh; and hereditary epistaxis (Osler's disease), by Herman Goldstein. The section entitled "Medical trend" contains an account, by the editor, of the meeting of the British Medical Association at Montreal in July, 1897, and some personal reminiscences of Sir William Osler, including his painful experience of obstetrics in country practice.

In his little book on *Tobacco*,[8] which forms No. 17 of the Harvard Health Talks, Dr. WALTER L. MENDENHALL, professor of pharmacology in Boston University, gives a judicial account of the various aspects of the tobacco problem, including its early history, the economic aspects, the effect of smoking on the circulatory system, alimentary tract, respiratory tract, eyes, and nervous system. An interesting description is given of the author's experiments showing that the main effect upon the nervous system is a sedative or depressant one, although it may have a stimulating effect as well. He comes to the conclusion from a study of the literature that there is no scientific evidence to support the claim that tobacco stunts growth. As regards the effect of tobacco on scholarship, comparative observations on smokers and non-smokers indicate that it is not so much tobacco itself that is the cause of a lower scholarship, but rather the associations and distractions accompanying the habit. After emphasizing the need for abstinence from tobacco in children, the author deals with the nicotine content of various brands of tobacco, and points out that denicotinized tobacco appeals as little to the smoker as does beer from which alcohol is absent, though he thinks it may be possible to obtain a tobacco which is free from nicotine and which yet retains its aroma.

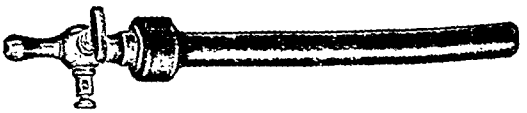
PREPARATIONS AND APPLIANCES

A FLUSHING ELECTRODE FOR TREATMENT OF ULCERATIVE COLITIS

In his article on the treatment of ulcerative colitis (*British Medical Journal*, October 18th, 1930) Dr. Julius Burnford referred to a special applicator manufactured by the Medical Supply Association, Ltd., Gray's Inn Road, W.C.1. This electrode comprises an inlet nozzle for the zinc solution, an inlet and outlet tap, with a connecting terminal for the



source of the electrical energy, and an insulated mantle covering the zinc rod (not seen in the illustration). The zinc solution passes through the apertures at the end of the insulating mantle into the colon, and the height is regulated by the douche-can reservoir containing the solution to which the applicator is attached.

NEO-INFUNDIN

Neo-Infundin (Messrs. Burroughs Wellcome and Co.) is a preparation of the oxytocic principle of pituitary posterior lobe almost free from the pressor principle. The preparation contains 10 international units per c.cm., and is supplied as a "hypoloid" product in phials of 0.5 and 1 c.cm.

"DISPERT" PRODUCTS

"Dispert" products are manufactured by the Krause Medico-Gesellschaft, and the agents in this country are Messrs. Coates and Cooper. These products are tablets of drugs which have been dried by the Krause desiccation process, which is a modification of one of the spray methods used for producing dried milk. The process ensures drying in a fraction of a second, before there is sufficient time for chemical or thermic influences to have any effect. Among the drugs thus prepared are the following: digitalis dispert, prepared in tablets each of which contains 150 frog units and is equivalent to one medium therapeutic dose; valerian dispert, a dry extract of the valerian root. The therapeutic value of preparations of the latter drug has been widely questioned in recent years. The makers claim that this is because most of the active principles are destroyed by the usual methods of preparation, and that these active principles are present in their preparation. The "dispert" method has also been employed in making preparations of various organs, such as the thyroid and pancreas.

British Medical Journal

SATURDAY, MARCH 7th, 1931

MEDICINE AND STATECRAFT

Under titles which at first sight would seem to connote a similarity of content there have recently been published two articles to which attention may well be directed in a medical journal. One is by Lord Dawson in the *Atlantic Monthly* for February, entitled "Medicine and Statesmanship"; the other is by Sir Walter Fletcher, in the *Listener* of January 28th (a reprint of his broadcast lecture), entitled "Biology and Statecraft." The subject-matter of the two articles is, in fact, quite different, but the practical applications of both have much in common. Each emphasizes the need for scientific knowledge, or at least for awareness of the importance of medical and scientific problems, in our statesmen and politicians. It can be said with truth that this has hitherto been conspicuously lacking, either because the education of men aspiring to public life was altogether inadequate, or because their education was too narrowly classical. As Sir Walter Fletcher said to his audience, "If you look back over the past half-century or more, a period of rapid scientific development unequalled in the world's history, you will find how rare it has been for any Cabinet Ministers in that time to have possessed a personal understanding of the methods and results of natural science."

The general lines of Lord Dawson's argument, and the propriety of his analogy between medicine and statesmanship, appear to be unimpeachable. Until late in the last century statesmanship thought in terms of individuals, and liberalism achieved success in its great fight for democratic government, freedom of conscience, and equality of opportunity. Medicine, also, regarded illness as almost wholly an individual matter. Since then there has come a much wider appreciation of the communal and preventive aspects of medicine, and statesmanship has increasingly assumed parental and even grandmotherly functions towards both the individual and the community. Lord Dawson pertinently asks, "Is the result of this tendency as good as its purpose?" and suggests that a study of the governance of the human body may prompt useful reflection. With full regard to public health, the presence of illness and the diagnosis of disease yet present to the doctor in every case a problem of individuality. "Should not personality and the rich variations of individual life be equally an object of care to the statesman?" In the very widespread attempts at social legislation now prevalent, it is essential that personality should be remembered and the varying needs of separate men and women taken into account. The standardized care of the State may easily enslave the individual; and the more remote the control the more likely is this to be the case, for there is no human contact between the controlling legislative or administrative hand and the person. Governments, by the very extent of their activities, are forced to use mechanical methods. They need "smaller groupings in which the skilled helper, inspired by human interest, would play a part." This is an effective plea for fuller and more appropriate use of the technical expert and the voluntary worker in the administration of public utilities and welfare schemes, and in such matters as the purchase and disposal of radium. "Would not the State," asks Lord Dawson, "like the higher centres of the brain, sometimes fulfil its function better by direction rather than administration, and by encouraging variations within its general control? While retaining the reins of policy and securing adequate responsibility, could not statesmen delegate many of the great problems that come before them to other bodies, small in number of members and containing experts endowed with the necessary skilled knowledge—bodies sufficiently independent to be uninfluenced by political exigencies and to be able to take the long view as regards public policy?"

The vast importance of medical and biological problems to Great Britain and the Empire, and the proper place of the scientific expert in their solution, are powerfully set out by Sir Walter Fletcher, who also exposes the almost complete failure of statesmen to appreciate the position and its possibilities. The illustrations he uses are the struggle between man and the insect, with its vital consequences in the spheres both of economics and of health, and the new knowledge of genetics, with its decisive practical bearing on the improvement of stocks of all kinds—vegetable, animal, and human. "We have a host of dangerous enemies despoiling us, and have no adequate policy of defence." This is true in the sphere of health: in that of economics "we are fast allowing the lead to pass to other countries who compete with us in the world markets." Though of all nations of the world "none has so great a need as England of bringing biology into her statecraft," yet those who are responsible for home, Indian, and colonial affairs fail to see the paramount importance of these problems, while other matters of relatively trivial consequence appear to engage their constant attention.

THE ELECTROCARDIOGRAM

Dr. W. H. Craib's recent publication on the electrocardiogram,[1] setting forth his most important research on numerous problems of academic and practical interest, has arrived at a most opportune moment, for it has been becoming more and more desirable to review the general position of the subject as it affects clinical practice. Moreover, his methods stress the importance to the research worker of knowledge outside his special branch, especially those fundamental principles of general physics which this author has been so successful in applying to physiological problems, and which have enabled him to obtain results of the greatest significance.

[1] Medical Research Council. Special Report Series, No. 147. The Electrocardiogram. By W. H. Craib. London: H.M. Stationery Office. 1930. (1s. 3d. net.)

But before attempting to summarize the most important of them it would seem expedient to state shortly what the tenets of academic and clinical electrocardiography are.

In the last decade two schools of thought and practice have come into existence, each holding different views on the value of the electrocardiogram. The English school holds that the electrocardiographic examination of the heart has enabled us to identify all the known clinical forms of irregular heart beat; that it now remains as a little-needed final court of appeal in difficult questions of rhythm when other means of solution fail; and that its sphere of utility is almost confined to the laboratory, where it may be expected to assist the elucidation of the academic problems of what used to be called "muscle and nerve physiology." The other school, whose more vociferous adherents are to be found in the United States, though enthusiastic members are to be found in large numbers in every country in Europe, consists of cardiologists who would employ the galvanometer in a more extended application to myocardial disease, and to whom the electrical record of a regularly beating heart affords information on the past and future history of the myocardium. The attempt to regard cardiology as a specialized branch of internal medicine has conduced very largely to an exaggerated use of the galvanometer in diagnosis; the English school finds the instrument invaluable in a limited number of cases, while the other school endeavours to wring from it information which is either already available through simple clinical channels or is unobtainable in the present state of medical prognosis. In the list of leading factors in cardiac diagnosis and prognosis, rhythm, to the examination of which the galvanometer is suited, is a relatively unimportant one, perhaps of less significance than the functional capabilities of other organs of the body.

In academic physiology Dr. Craib has been studying the changes in electric potential which are brought about by the passage of a wave of excitation along a strip of tissue. This is not new. When the phenomena were first studied many years ago it was thought that an ultimate explanation of many biological processes in terms of electric currents had been foreshadowed, and, although these hopes were never realized, the subject remained sufficiently attractive to physiologists (it made a greater appeal to the imagination than the observation that sound accompanied the contraction of a muscle) for some progress in muscle and nerve physiology to be made; instruments and methods were improved, and more applied research culminated in Sir Thomas Lewis's work on the disordered heart beat in man. Those studying what have once more become academic problems from 1921 cannot be said to have made any striking announcement till now, when we find that some of the once well-established facts of physiology are capable of, and indeed demand, other interpretations. Dr. Craib has not been content to remain a physiologist; but, thinking as a physicist when using the latter's appliances and methods, he has reaped a rich harvest of interesting results. The physiologist must be more than a physiologist, if he can find time, otherwise his results will rest on an insecure foundation, open to attack from any of the quarters whence he has borrowed his methods, be they physical or chemical. Non-polarizable electrodes have for decades been placed in contact with strips of tissue moistened or immersed in saline, but it has till now remained unnoticed that the potential changes at the electrodes are directly related to the electric field in the saline, and not to that in the tissue, of which we know nothing at present except by inference and interpretation.

It has been taught in the past that an active tissue, or portion of tissue, is electrically negative to inactive tissue. Dr. Craib draws from a very simple experiment in the almost intact frog the unequivocal conclusion that active tissue is electro-positive to inactive tissue. He then shows that when a wave of excitation passes along a strip of muscle or nerve the potential changes in the electric field set up in the surrounding medium are such as would be expected by postulating the progress along the tissue of a series of ring-like "doublets" of simultaneous anodes and cathodes, so orientated that the anodes (positive) precede the cathodes (negative); these doublets of invasion are followed by doublets of retreat (to employ a well-known form of expression), in which the relative position of anodes and cathodes is reversed. His plan has been to study experimentally the distribution of potential in a large conducting medium surrounding a doublet, represented by an inanimate pair of non-polarizable electrodes, connected to a battery, and placed in contact with a circular pad of filter paper moistened with saline, and also to investigate the distribution of potential in a linear conductor, consisting of a thread previously moistened with saline and supplied with stationary doublets in the form of pairs of non-polarizable electrodes. It should be clear that the environment of the conductor in the first experiment corresponds closely to that of a preparation immersed in saline, or to the conditions prevailing in the intact body; the second experiment schematizes the familiar strip of tissue just moistened with saline and suspended in air, to which a living analogy is wanting. From the information so obtained he has been able to interpret his experimental observations on muscle and nerve.

A stupendous amount of research has been done on the "monophasic response." The interest of the attempt to record the exact form of the potential changes under *one* contact when a wave of excitation passes lies in the assumption that this form would eventually reveal what excitation really was, in more or less ultimate terms. There is no need to describe how the experiments were done; it may suffice to say that the second contact was placed upon tissue which had been previously injured and therefore served only as a second lead to the galvanometer. It is at once apparent from the work under consideration that these painstaking efforts were inspired by the false assumption

that the electrodes recorded what was passing in the tissue itself, whereas they can never do so directly. Dr. Craib has, however, studied the conditions which determine the monophasic response from two contacts placed on a strip of tissue, and, as he summarizes them, they are: "(*a*) that the strip should be bathed by a mere pellicle of fluid only; (*b*) that in a large strip the excitation wave should involve all the fibres; and (*c*) that the impulse should die out between the contacts at a region displaying conspicuous current of injury, . . . nor is it necessary that one of the contacts should rest upon destroyed tissue."

The observations on the responses of immersed tissues help to clear up several difficulties in the interpretation of the electrocardiogram, and the important conclusions are reached that the electrocardiographic deflection at any moment depends on the direction at that moment of the excitation wave through the myocardium (a confirmation of views already expressed long ago by Sir Thomas Lewis); that there is no relation between the voltage of the electrocardiogram and either the weight or the strength of the muscle; that a large myocardial infarction, as dramatic an accident as could happen in this circumscribed area, might occur in a region of the ventricle where the wave of excitation passed in a direction perpendicular to the plane of the leads without affecting the galvanometer, unless gross changes in the action of the heart ensued. From this research no support is forthcoming for an extension of electrocardiographic methods to a routine study of the myocardium.

THE SERVICE REPORTS

In recent issues we have published reviews of the annual reports for 1929 on the health of the Navy and the Army. Dealing with the incidence of disease in a selected population, these reports are instructive, but as uniformity in the method of presenting the respective figures is lacking, they fall short of achieving the maximum of interest and value. We understand that in certain areas and Commands the sick and injured of the Navy, Army, and Air Force are treated in one hospital. This procedure leads to economy, efficiency, and co-operation. There is also a committee composed of the administrative heads of the different medical services, whose duty it is to promote further co-operation. We would suggest that there is scope for the powers of this committee in the method of preparing the annual health reports. All the Services now produce their reports at approximately the same time. Surely it would be a simple matter to combine these reports in one volume, dealing with the statistics of the respective Services in separate sections. One of the advantages which would be gained from this method would be the attention it could focus upon the chief causes of inefficiency and loss of personnel. It appears that the outstanding causes of disablement in the Services are injuries, venereal diseases, and the ordinary ailments of everyday life. As everyone knows, serving officers and men of the fighting forces must be kept physically fit by drills, exercises, and the different forms of athletic sports, and in the nature of things they are more liable to injury and accident than the average civilian. It would be absurd to suppose that injuries in the Services can be wholly eliminated, but we may recall that much was done to reduce certain injuries in the Air Force a few years ago by preventive measures suggested by statistical research. To-day the chief causes of invaliding out of the Services are pulmonary tuberculosis and otitis media. These diseases require further investigation if loss to the State is to be curtailed. It will be noted in the reviews we have published that the naval medical authorities record an average of nineteen days for the treatment of gonorrhoea, while in the Army the period of treatment for the same disease is approximately three months. This discrepancy suggests that there is room for exchange of views between the medical officers most concerned. Combination of the health reports of the several Services, following a uniform method of production, need not deprive the individual records of their own characteristics; it would tend, rather, to bring to light such important points as those we have mentioned for the benefit of all officers. A broader and more comprehensive outlook would, in time, enable all three Services to achieve even higher ideals in medical work, and to promote further efficiency and economy.

VITAMINS AND SUBACUTE COMBINED DEGENERATION OF THE CORD

Professor Edward Mellanby, in a lecture delivered last summer in America,[1] has given a short account of some of the evidence he has obtained concerning those rather mysterious toxic substances in the germ of cereals whose action is antagonized by vitamins. A few years ago he aroused consternation and indignation in Scotland by pointing out that oatmeal contained some substance which favoured the appearance of rickets. His more recent work concerns the action of certain unknown toxic substances on the central nervous system. The addition of ergot to the diet of puppies was found to produce subacute combined degeneration in the spinal cord, provided that the diet was devoid of fat-soluble vitamins, but these changes could be prevented by administration of either vitamin A or carotene. Similar effects were produced by rye germ or by wheat germ. Subacute combined degeneration of the cord is found in the following clinical conditions: (1) nervous ergotism, (2) lathyrism, (3) pellagra, and (4) pernicious anaemia. The experiments described provide an adequate explanation of outbreaks of nervous ergotism, for these are likely to occur whenever ergotized rye is eaten by a population whose diet is poor in animal fats. It seems probable that lathyrism may arise from similar causes. Professor Mellanby also suggests that pellagra may be due to a twofold vitamin deficiency—a deficiency of vitamin B_2 (alias P-P or G) which causes the skin changes, and of vitamin A which allows nerve degeneration to develop. He suggests, further, the possibility of a double deficiency in pernicious anaemia—namely, a deficiency of the water-soluble substance obtainable from liver which causes blood changes, and of vitamin A which causes lesions in the central nervous system. These speculations are of very great interest, and fortunately it should be a fairly simple matter to test them clinically.

[1] *Journ. Amer. Med. Assoc.*, 1931, xcvi, 325.

INSANITY AMONG THE SCANDINAVIANS

The common mistake of grouping all the Scandinavian nations in one and the same ethnical unit has arisen partly because the Scandinavian languages are so much alike that one Scandinavian understands another even when he speaks in his own tongue—a generalization which does not, however, apply to the languages of Finland and Iceland. Behind this community of speech—this "Lingua Scandinavica"—there are fundamental racial differences which show themselves even in the forms of insanity most common in the different countries. This curious point is brought out in a paper in *Nordisk Medicinsk Tidsskrift* for January 24th by Dr. K. A. Andresen, who shows that the incidence of all forms of insanity is considerably higher in Norway than in Denmark. According to the Norwegian census of 1920, and the Danish census of 1921, there were 8,602 lunatics in Norway and only 6,255 in Denmark, although the population of the latter country was then 3 million, compared with a little over 2½ million in the former. Differences in the rate of insanity between the sexes in the two countries were also found to be very marked; in Norway the number of insane males was 48 per cent. higher than in Denmark, whereas the insanity rate for females was only 29 per cent. higher. While there were 325 lunatics in Norway for every 100,000 inhabitants, the corresponding figure for Denmark was 201. A similar difference was observed in the case of mental defectives, of whom there were 6,571 in Norway and 4,988 in Denmark, where the care of mental defectives is highly organized. More than three-fifths of the mental defectives are specially cared for in Denmark, while in Norway 90 per cent. of them lack special provision. The difference in the incidence rate of insanity between the two countries can be traced back many decades; in 1865 the figure per 100,000 was 185 in Norway; in Denmark in 1860 it was 117. Since then practically every census has revealed a parallel rise in this rate, with Norway always well ahead. In regard to the sex incidence of insanity in each of the countries, there were only 100 insane males to every 130 females in Denmark, whereas in Norway the ratio is 100 males to 113 females. The predominant type of insanity in Norway and Sweden is dementia; in Denmark it is the manic-depressive type. In fact, dementia would seem to be about twice as common in Sweden as in Denmark. One reason for the incidence of insanity in Denmark appearing to be so much lower than in the other two Scandinavian countries is that many of the patients with manic-depressive psychoses are not registered as lunatics at any given census, this malady, in contrast to the dementias as a class, being often transient. It has been suggested that the high insanity rate of Norway and Sweden may be explained by the devitalizing effect of emigration, continuing generation after generation, but the incidence of insanity among Norwegians and Swedes is very high in the United States. According to a Norwegian-American writer, 1 out of every 252 Norwegians in the United States is admitted to some public asylum, the corresponding proportion for the total population being only 1 in 627. Dr. Andresen is inclined to trace these remarkable differences between Norway and Sweden on the one hand, and Denmark on the other, to differences in character, which in their turn depend on fundamental racial differences. The Nordic type is purer in Norway and Sweden than anywhere else. The Dane is a most complex ethnical mosaic, to the pattern of which the Alpine type has contributed not a little. The dour and introspective Norwegian or Swede differs greatly from the lively and emotional Dane, who suffers from the defects of his qualities, for the emotional element in his character leads him into such excesses as suicide. In 1924, for example, there were 462 suicides in Denmark as compared with 158 in Norway.

SHORTAGE OF NURSES

The maintenance of an adequate nursing service in the hospital and elsewhere is of the utmost concern to medical men. In this belief, the *Lancet* Commission on Nursing was set up, under the chairmanship of the Earl of Crawford and Balcarres, to inquire into the shortage of candidates, trained and untrained, for nursing the sick in general and special hospitals throughout the country. The first meeting was held in December, 1930, when it was decided that the initial step must be to ascertain whether an absolute shortage of candidates existed, or whether the shortage was only among candidates whose education and personal qualities made them likely to become satisfactory nurses. After consideration of the best way to approach the problem, a questionary was sent out to the responsible authorities of over 1,200 institutions in Great Britain and Ireland; these included all the hospitals approved as training schools by the General Nursing Councils of England and Wales, Scotland, and Ireland, and a certain number of hospitals not approved as training schools in various counties in the British Isles. As there was reason to think that tuberculosis hospitals and sanatoriums found greater difficulty in obtaining recruits to their nursing staffs than any other type of hospital, forms were sent to more than one hundred and twenty such institutions. The information asked for covered the degree of shortage of probationers and trained nurses experienced by the institutions addressed, and the conditions of life and work of the nurses; space was provided for opinions on the reasons for the shortage. A statistical analysis of the replies received was undertaken by Mr. A. Bradford Hill, D.Sc., and the first interim report on the inquiry appeared in the *Lancet* of February 28th. Dr. Bradford Hill's preliminary report shows clearly that a shortage of candidates does exist, in that one-half of the hospitals whose replies have been analysed fail to secure probationers and staff nurses of the standard they require; as might be expected, the shortage is least acute among the London voluntary hospitals, but even here one-third are unable to find suitable staff nurses and one-quarter have difficulty in engaging probationers. The educational level required of probationers in the municipal hospitals is not so high as in other classes of institution so far studied; two-thirds of the municipal hospitals accept probationers who have reached the seventh standard, while only one-quarter of them aim at candidates with secondary education. Among certain other classes of hospital whose replies have been analysed the proportion requiring secondary education is three-quarters. Many hospitals aim at "secondary education, if possible," suggesting that in

order to obtain sufficient staff they have to be content with a lower standard. In giving reasons for the shortage many of the replies stress the occupations with better financial prospects which are now open to women, and the long hours and restricted freedom which fall to the lot of the nurse.

THE FRACTIONAL PRODUCTS OF THE TUBERCLE BACILLUS

One of the striking characteristics of the tubercle bacillus is that, unlike most other micro-organisms, when inoculated in the killed condition into animals it gives rise to little or no active immunity. Among the reasons that have been suggested to account for this behaviour, one of the most probable is that the bacilli are not broken up sufficiently within the normal animal to lead to liberation of the specific antigen necessary for the requisite stimulation of the body cells. If the bacilli could be disintegrated *in vitro* and the specific antigen isolated in relatively pure form, it is conceivable that more favourable results would follow its injection than that of the whole bacillus. So far this has not been accomplished, but the co-operative study that has been carried out in the United States during the past five years under the direction of the Research Committee of the National Tuberculosis Association leads one to hope that it may not be long before this objective is realized. A recent publication[1] by Sabin, Doan, and Forkner, of the Rockefeller Institute, describes the results of the biological testing of certain products isolated from the human tubercle bacillus by Anderson and his colleagues at Yale University. Briefly, it has been found that the lipoid fraction is alone responsible for the production of specific tubercular tissue. Of the various fractions isolated, the phosphatide was the most active; its injection intraperitoneally into rabbits was followed by the extensive development of epithelioid and of giant cells. Analysis of the phosphatide, and of certain other of the lipoid fractions, revealed the presence of an optically active saturated fatty acid, which is termed "phthioic acid." The injection of this substance likewise led to the formation of tubercular tissue, particularly in the shape of localized aggregations closely simulating true tubercles. Neither the tuberculo-protein nor the polysaccharide isolated possessed this specific cellular stimulus. The protein proved highly toxic to tuberculous animals, and it would seem probable that both it and the polysaccharide are concerned, not in the production of tubercles, but in the development of allergy. The formation of tubercular tissue seems to depend on the lipoid fraction, the active principle of which is the newly isolated phthioic acid.

NATURE OF THE LIVING CELL

At the February meeting of the Royal Microscopical Society Dr. Robert Chambers, professor of biology in the University of New York, gave a remarkable demonstration of his method of micro-dissection and micro-injection, in an address on the nature of the living cell. One of the most striking peculiarities of protoplasm is the fact that it exists only within the confines of microscopic dimensions. Protoplasm is protoplasm only in the form of living cells, plant or animal; therefore the only direct method of studying its properties is through the compound microscope under magnifications varying from 150 to over 1,000 diameters. The micro-dissection and micro-injection technique of Professor Chambers was evolved in order to make it possible to manipulate the protoplasm within the living cell. The apparatus is a mechanical device for controlling the movements of glass-spun micro-needles and pipettes within the field of the microscope. An apparatus of this kind, built in 1920, was first demonstrated before the Royal Microscopical Society about six years ago. Since then several different types of instrument have been developed by various workers. The present apparatus is based upon the original model of 1920, but it has been modified from year to year by the addition of various improvements, and is so constructed as to permit operations upon the living cell under the highest magnifications. By means of this instrument a great many new facts have been discovered regarding the physical and chemical properties of protoplasm. We now know, for instance, that the nucleus in many cells is a fluid body, and is more alkaline in reaction than the cytoplasm in which it is immersed. The oxidation intensity of living protoplasm has also been determined by the injection into the living cell of dyes which are reducible. For example, when the colour disappears on injection, and can subsequently be made to reappear by the injection of an oxidizing agent, we can be fairly certain that the protoplasm had reduced it in the first instance. Similarly, by this method, the physical properties of the hitherto hypothetically regarded cell-membrane have been made the object of intensive study.

INTERNATIONAL TRACHOMA PRIZE

The Hungarian Minister of Public Welfare and Labour offers a prize of 2,000 Swiss francs as a reward for original work on the etiology of trachoma. Essays intended for the competition must be addressed to Eye Clinic No. 1 of the Royal Hungarian Peter Pázmány University, Budapest (VIII, Mária-utca 39) not later than June 30th next. Works that have already appeared in print are eligible equally with essays specially written for the occasion. The jury of award may also consider works not submitted for competition but appearing in print between July 1st, 1929, and June 30th, 1931. Essays submitted may be written in German, English, French, Italian, or Hungarian. The jury of award is appointed by the Minister, and consists of Mr. A. F. MacCallan (London), Dr. Victor Morax (Paris), Professor L. Maggiore (Bari), and Professor Carl Prausnitz (Breslau). Its decision will be announced not later than December 31st, 1931.

We regret to record the death, after many years of ill-health, of Mr. Douglas Drew, consulting surgeon to the Queen's Hospital for Children, and the Hospital for Women, Soho.

A lecture under the Chadwick Trust on maternal mortality will be given by Dame Louise McIlroy in the Great Hall of the British Medical Association House, Tavistock Square, on Wednesday, March 11th, at 5 p.m. The lecture is free, and no tickets are required.

MEDICAL RESEARCH COUNCIL

ANNUAL REPORT, 1929-30

I

The sixteenth annual report[1] of the Medical Research Council, which was issued this week, records advances in many departments of research, several of which are of immediate interest to general practitioners. The usual annual grant by Parliament of £148,000 was devoted as follows: £86,000 to general scientific investigators, for research work in clinical medicine, and for the work of the Industrial Research Board; £52,000 for the expenses of the National Institute for Medical Research at Hampstead and of the farm laboratories at Mill Hill; and £10,000 for administration. In addition to this grant, financial help for special purposes was received from various sources, including the Miners' Welfare Fund, the Empire Marketing Board, the Dental Board of the United Kingdom, the British Empire Cancer Campaign, the Distemper Research Council of the *Field*, and the Foot-and-Mouth Disease Research Committee. The Council is co-operating closely with the Ministry of Health and the Scottish Department of Health, and is directly represented on the Scientific Advisory Committee set up last autumn by the Secretary of State for Scotland. In the past year Sir Frederick Hopkins and Sir Charles Martin retired from the Council under the terms of the Royal Charter; Sir Charles Sherrington, who retired in 1929, was reappointed, and Dr. J. A. Arkwright became a member.

GENERAL SUMMARY

The increased responsibility of the Medical Research Council in respect of work within the range of the Therapeutic Substances Act is manifest in the report. Advice has to be given on the routine administration of the Act, and active research work is in progress concerning the preparation and use of standards of reference for the proper assay of biological substances which cannot be measured by direct chemical means. Special attention is also being devoted to the study of the accessory food factors, and it is confidently hoped that in this way Great Britain will play an honourable part in the further development of a branch of medical science which is now receiving special attention in several other countries.

The appointment of Sir Thomas Lewis last June as physician in charge of the Department of Clinical Research at University College Hospital is mentioned in the report as a forward step of the greatest importance, indicating the value of such a research organization; the creation of a position which will appeal to the ambition of younger workers hereafter should stimulate clinical research throughout the country. Somewhat similar appointments are contemplated at Leeds, Birmingham, and Aberdeen, reproducing conditions such as exist already at Sheffield, where the professor of pharmacology, Dr. Edward Mellanby, has had charge of forty hospital beds for the past ten years. Last year the report of the Medical Research Council reviewed the efforts it had made to assist the scientific development of clinical work as such; it is now pointed out that the establishment of such new posts, in which men freed from the claims and restrictions of private practice may devote their whole energies to the advancement of clinical medicine by research within the hospitals, calls urgently for further endowments.

Puerperal Infections

Maternal mortality and puerperal fever have for long engaged the close attention of the Council, and a special committee has been at work supervising the study of streptococci. The concentration of cases for observation has been made more possible at Manchester, where a 50 per cent. reduction in the mortality was thus achieved. In this connexion reference is made in the report to the removal of Queen Charlotte's Hospital to Hammersmith, where already a special block for the aggregation and treatment of septic cases has been built and equipped with suitable laboratories for bacteriological and biochemical work. The Council is assisting the hospital in this undertaking; Dr. Colebrook, working in the Council's service, will act as honorary director of the laboratories, and as consulting pathologist will co-operate with the clinical staff. The belief is expressed that definite knowledge is steadily accumulating as regards the adoption of valuable preventive methods, but the curative aspect is less hopeful. Thus Dr. Colebrook has been investigating the efficacy of different methods for the sterilization of the hands in midwifery, and has also revealed the fact that puerperal fever cases not infected with haemolytic streptococci frequently harbour gas-forming anaerobic streptococci.

Nutrition Studies

Much recent work has been devoted to vitamin A, which probably represents a main constituent of the original "growth factor" first demonstrated by Sir Frederick Hopkins in 1912. An ample supply of the special concentrate of this substance has now been obtained by the Council, and carefully controlled investigations will be conducted to determine whether it is really the case that this vitamin has a primary value, both in defending the body against infective diseases and also in promoting recovery after infection has become established. Thus it has already been possible to test it on a large scale in the prevention of colds during the winter months, under various conditions of indoor and outdoor work. Another inquiry in progress is an examination of the possibility that this vitamin may have some value in the treatment of infective middle-ear disease after scarlet fever, and in the prevention of dangerous infective sequels after the common infective fevers. Again, at the Dunn Nutritional Laboratory, recently completed and equipped at Cambridge, work has been in progress on carotene, the yellow pigment which produces effects closely resembling those of vitamin A. Pure recrystallized carotene can effectively replace vitamin A in the diet, and it had been concluded that it was stored unchanged in the liver. Dr. Moore, working for the Council in the Dunn Laboratory, has shown that the effects following ingestion of carotene are not due to its being stored in the body, or to any identity with vitamin A, but that carotene in the diet leads to a proportionate appearance of vitamin A as such in the liver fat. His work suggests strongly that carotene is a precursor of this vitamin, and leads to its production within the animal body. This affords an explanation of the fact previously demonstrated by Dr. Moore that the carrot, which contains carotene in abundance but no vitamin A as such, can give rise to the production in the animal body of as much vitamin A as that contained in an equivalent weight of cod-liver oil, calculated as dry substance.

Progress has also been made in the standardization of vitamin preparations. The discovery, made in the Council's laboratories at the National Institute, of the method of producing vitamin D artificially from ergosterol has led to its manufacture on an extensive scale, its issue in many forms for therapeutic use, and its addition to many types of food materials. An attempt to indicate the degree of activity of various such preparations has led to the appearance of several unofficial so-called "units," with no clearly defined relations. It was

[1] Cmd. 3785. Report of the Medical Research Council for 1929-30. London: H.M. Stationery Office. 1931. (2s. 6d. net.)

accordingly arranged to maintain at the National Institute a standard solution of irradiated ergosterol to facilitate the comparative estimation of vitamin D. The unit of this vitamin was defined as the antirachitic potency of a quantity of the first-named preparation, corresponding to 0.0001 mg. of the ergosterol used in its production. Methods were devised for thus estimating vitamin D, and supplies of the standard material were made available for general distribution to approved users last August, since when samples of the standard have been sent to twenty-eight institutions in Great Britain and to eight other countries. To promote the studies necessary for the establishment of other standards subcommittees have been already formed by the Accessory Food Factors Committee to deal with vitamins A, B_1, and C; they are actively at work.

Alcohol and Fertility

An experimental estimation of the effect of alcohol on the fertility of guinea-pigs has just been concluded at the National Institute, after having continued for nine years. In 1913 and 1914 Professor Stockard, in America, published the results of a similar experiment, his records seeming to prove that the daily administration of alcohol in quantities large enough to produce visible intoxication, but not otherwise to impair the health of the parents, caused a fall in the number of births, an increased liability to stillbirths, and the production of weakly and defective offspring. A still more serious point was that these tendencies appeared to be inherited, so that without further exposure of the stock to alcohol the proportion of animals showing weakness and deformity continued to be high in later generations. Stockard's results clearly suggested that alcohol in the circulation could injure the germ plasm, and bring about permanent deterioration of the race, even without obvious injury to the generation directly exposed. It was unlikely that alcohol would be the only poison acting in this deferred way; it was, indeed, quite possible that any circulating poison, such as those occurring in the acute infections, might inflict similar damage, only recognizable in later generations. So grave a threat to the future of humanity necessitated the careful repeating of Stockard's experiments, and this has now been done.

Miss Durham, using a specially chosen stock of guinea-pigs, has followed exactly Professor Stockard's lines, full controls being maintained. The diet was standardized for all the animals, care being taken to ensure an adequate ration of the essential vitamins. The results were statistically analysed, but no confirmation was obtained of a single essential point of Stockard's findings. The litters obtained from alcoholic parents, or from their descendants, were as numerous as those from the control matings; there was no excess of stillbirths or deformity. Their offspring for several generations exhibited no transmitted defects of the kind described by Professor Stockard, from which it appears that those defects were not attributable to the alcohol. This section of the report closes with the pertinent remark that "these negative findings have no relation whatever to the effects of alcoholic parentage on the upbringing of children in an organized human society."

[To be concluded]

The sixteenth Congress of French-speaking Medical Jurists will be held in Paris from May 25th to 27th, when the following subjects will be discussed: medical study of motor accidents, introduced by M. Simonin; traumatic ulcer of the stomach, introduced by M. E. Martin; crimes due to passion, introduced by M. Lévy-Valensi; and medical responsibility, introduced by MM. Duvoir and Donnedieu de Vabre.

THE SPLEEN: ITS STRUCTURE, FUNCTIONS, AND DISEASES

DR. McNEE'S LETTSOMIAN LECTURES

The Lettsomian Lectures were delivered before the Medical Society of London on February 16th and 25th, and March 4th. The lecturer was Dr. J. W. McNEE, who discussed the spleen, its structure, functions, and diseases.

HISTORICAL INTRODUCTION

In his first lecture Dr. McNee said that splenic enlargement presented itself as a clinical problem in all sorts of medical and surgical conditions. The subject of the spleen was a difficult one, and he might appear bold in attempting to give an account of its structure, functions, and diseases in three brief lectures. The matter, however, was one which, on the whole, was poorly understood, and seemed worthy of attention at the present time, because recent physiological and pathological researches had cleared up some points of difficulty and had indicated methods by use of which the solution of others might be expected. The human spleen was of considerable size, very easily accessible, and, when enlarged, palpable through the abdominal wall. Numerous records of curious beliefs and speculations about splenic function were found in the early history of medicine, but real knowledge of its intimate structure had accumulated slowly. One reason for this was no doubt the fact, established from the earliest times, that the spleen had not any function absolutely essential for life, so that some less fundamental reasons for its presence in the body had to be discovered. The spleen was described by Hippocrates, who stated that its work was to draw the watery part of the food from the stomach. Aristotle, in describing the organ, thought it had a somewhat similar function. Galen termed the spleen an organ full of mystery, and in the Galenic physiology it was associated with melancholia, a view which persisted for a thousand years. Numerous allusions having that significance were to be found in the works of Shakespeare and of other poets. In the first translation of Pliny into English, in 1601, there was a definite reference to the extirpation of the spleen in runners. There was a well-known tradition that in the earliest times Greek runners had their spleens removed in order to increase their speed and endurance. The first recorded splenectomies were carried out on dogs in 1680. Before that date Malpighi had ligatured the splenic vessels in dogs, without apparently injuring them, and later on he performed splenectomy in the same animals. The first operation for the removal of the human spleen was said to have been performed in 1549. Possibly the first human splenectomy carried out in this country was described by Dr. Timothy Clarke, who was physician to Charles II. Coming to modern times, Spencer Wells in 1866 operated on one of the first English cases in which the abdomen was deliberately opened and the spleen removed; in this case, however, the patient died. With the advent of Listerian principles, splenectomy became commoner, but the mortality at first was high.

The lecturer referred at length to the work of William Stukeley, who, in the introduction to his Goulstonian Lecture in 1722 to the Royal College of Physicians, on "The spleen: its description, history, use, and diseases," said that "the uses of the apparatus [the contents of the abdominal cavity] are by the industry of the curious pretty manifest, except that of the spleen; which yet has not failed to be a subject of inquiry in all ages, and has racked the brains of physicians as well as the bowels of their patients." Stukeley recognized that this spongy organ, when filled with blood, could by contraction

empty itself again at pleasure. He thought it acted as a diverticulum or safety valve to the general systemic circulation. "This necessary surcharge of blood is so regulated by the spleen as that no inconveniences arise from it"—truly an amazing prophecy of future discoveries. Just as Stukeley's work could be regarded as the classic reference on the spleen in the eighteenth century, so Henry Gray's book, published in 1854, on *The Structure and Use of the Spleen*, could be regarded for the nineteenth century, but Gray gave a much more passive role to the organ.

THE SPLEEN STRUCTURE

In dealing with the problems of the splenic structure, Dr. McNee said that in recent times much of the older work and its possible significance had been completely forgotten, and in most of the recent textbooks the description of the finer histology of the spleen was, on the whole, very poor and meagre. He was able to obtain a supply of animal spleens from the Zoological Gardens and from the Marine Biological Stations, and the comparative study of them had been of the greatest help. The following points in the structure of the spleen were, he believed, important in the interpretation of human splenic disease. The spleen of all vertebrates was covered by a fibro-elastic tunica propria, which in some animals contained abundant muscle fibres. In man the muscle was chiefly confined to the fibrous partitions known as the trabeculae of the spleen. The reticular network of the spleen was first described in 1847. It was a structure often misunderstood, but it was a most important element in the essential framework of the organ. Such tissue was not limited entirely to the spleen, but occurred in the liver, and also in the lung. The lobularity of the spleen was a most important fact to note; all spleens were essentially lobular in structure.

The lecturer dwelt at length on the blood supply of the spleen. The splenic artery in man was remarkable for its large size, as compared with the bulk of the organ. As a rule, it was a single vessel which broke up close to the hilum into a number of branches, but occasionally the branching took place at some distance before the hilum, and he had seen this lead to surgical difficulties at operation. The main branches of the splenic artery were tortuous and spring-like, and divided abundantly, until finally each branch bifurcated to form two slender vessels which were called penicilli. These were end arteries and did not anastomose. If blocked, they produced an infarction of the potential lobe supplied.

Another important part of the internal vascular arrangement of the spleen was the ellipsoid. The structure and significance of the ellipsoids had been fully investigated. They consisted of swellings of reticulum surrounding the penicilli at their terminations. They were present in the spleens of all animals, but varied greatly in their prominence. In the human spleen they could only be demonstrated with ease by impregnating the reticulum with Indian ink. The splenic vein was even more remarkable for its large calibre, in comparison with both the size of the organ and the size of the artery. It had enormous contractile power. He was convinced that most of the penicillar branches ended directly in venous sinuses, though he was well aware that there were opponents of that view. The spleen pulp constituted the spaces between the reticulum. The pulp spaces were the essential reservoirs of the spleen, and formed the largest part of the spleen structure. Turning to the problem of the mechanism of the splenic circulation, Dr. McNee said that this had been the subject of most acute controversy from the earliest developments of histology. He believed, however, that the comparative study of the spleen in animals explained some of the difficulties, while recent physiological researches had elucidated some others. Three views had been current: that the circulation was completely closed, that it was partly open and partly closed, and that it was completely open. In the comparative study of the spleen in animals it had been found that the circulation was obviously different in different species. In fishes there was an open circulation. In reptiles there was a closed circulation, being entirely within vessels lined by endothelium. In birds no conclusion could be reached, because the vessels were so fragile. In man it seemed impossible to solve the problem by direct histological methods, but help had come from the physiological researches of Barcroft on splenic function, which had suggested a form of two-way circulation in the human spleen, part passing straight through, and part being diverted into the pulp. He described some experiments of his own which, he thought, together with Barcroft's observations, strongly supported the view that there might be such a two-way circulation in man and the higher animals. The first or ordinary circulation went on continually as a direct one, the blood pumping straight through the splenic artery into the venous sinuses. The second circulation was intermittent, and was brought about by contraction and relaxation of the whole organ. It consisted of the emptying of the pulp spaces into the veins and their filling again through the lateral channels in the walls of the ellipsoids.

FUNCTIONS OF THE SPLEEN

In his second lecture, on February 25th, Dr. McNee began by remarking on the size and weight of the spleen. In vertebrates the weight of the spleen in comparison with the body weight varied enormously. It was relatively greatest in fishes and least in birds. Many observations on the weight of the human spleen at different ages were made by Henry Gray, who stated that the organ was largest during youth and active adult life, but in old age decreased in weight. Over the age of 60 the average weight was 4½ oz.

The first function of the spleen to which the lecturer alluded was its contractile power. The study of this subject was invested with new interest in 1923, when Barcroft and his colleagues at Cambridge began their important series of observations. In an expedition to Peru to study the effects of high altitude on man, Barcroft was puzzled, even on the voyage out, to account for the number of red corpuscles suddenly added to the blood as soon as hot weather was reached. Obviously this blood could only come from some storehouse or reservoir, and it was natural to think of the spleen. By a series of ingenious experiments Barcroft was able to show that a dog's spleen contracted actively during exercise, heat, and emotion, and his experiments with carbon monoxide poisoning also showed conclusively the sudden emptying of the spleen pulp during exercise. Binet and his colleagues in Paris from 1926 onwards approached the same problem from a different angle. They had noticed in experimenting with asphyxiating gases a sudden increase in the count of red corpuscles. The increase was very rapid, and the blood count of an asphyxiated dog might rise 1,000,000 or even 2,000,000 per c.cm. within five minutes. Binet soon found that in animals in which the spleen had been previously removed this increase in the blood count on asphyxiation failed to occur. Thus the contractile power of the spleen as an ancillary respiratory organ seemed completely proved.

Active contraction of the spleen had also been found to occur regularly after haemorrhage, but Barcroft had shown that this contraction was most important or pronounced after a single experimental haemorrhage and not when blood loss was repeated. While no one could fail to be impressed with the importance of the spleen

as a ready and rapidly available source of red blood corpuscles, the importance of the bone marrow as an additional source of supply must not be overlooked. Possibly the supply of red cells from bone marrow was not available so promptly as from the spleen, but none the less there must be in the normal bone marow a large store of ripe or nearly ripe red blood corpuscles.

The actual mechanism whereby splenic contraction and relaxation was brought about was of considerable interest. Binet concluded that there was a centre for splenic contraction in the medulla which acted by the stimulus of asphyxiation or changes in blood pressure. Obviously this central nervous mechanism was very complex and far from being understood. Apart from this probable nervous mechanism of contraction, there was a second mechanism whereby the spleen could certainly be made to contract under normal circumstances—namely, by the liberation of adrenaline into the blood, and it was almost certain that this mechanism operated in exercise and emotion.

It was now generally accepted that during foetal life the spleen, together with the liver, actually manufactures blood corpuscles of every kind, and in post-uterine life a reversion to this occurs in a variety of diseases of the blood. This so-called myeloid metaplasia had been studied by many workers. Lymphocytes were believed to be supplied to the blood by the Malpighian bodies during life, but there was still a good deal to learn about the physiology of the lymphatic system. Following splenectomy in normal animals a definite anaemia supervened. The cause of this long-persisting anaemia was not fully understood, but it occurred after splenectomy in human cases. Possibly it was due to the loss of some stimulating effect on the bone marrow. The lecturer went on to discuss the relation of the spleen to blood platelet production and destruction. It was most unfortunate that information on this subject was so inexact. The problem really first came forward after the apparent cure by splenectomy of severe cases of purpura associated with very low platelet count, and the marked rise in the count suggested that the spleen might either destroy the platelets or influence their production in the bone marrow.

He added a word or two about the relation of the spleen to digestion. It had been thought from the earliest times that the spleen was in some way related to the digestive process. Alterations in size of the spleen had been long noted to occur during digestion. It might be said that most of the recent studies had shown that all the metabolic processes of digestion were in no way changed in animals after splenectomy. The question of fat metabolism had been particularly investigated. It was known for a long time that the cholesterol content of the plasma was reduced in pernicious and secondary anaemias, but rapidly increased after splenectomy took place. The whole question of the relation of the spleen to fat metabolism definitely required reinvestigation, and there was a very good clinical reason for such reinvestigation, because there were a number of conditions in which it might be important to know more about the normal fat metabolism so far as the spleen was concerned.

As to the relation of the spleen to the processes of immunity, it seemed probable that the reticulo-endothelial system of cells was in some way connected with immunity to infection, so that the spleen must be regarded as of some importance in that connexion. The important clinical point arose naturally as to whether infectious diseases were commoner or were less well resisted in spleenless individuals; there was very little in the literature about that subject. On the subject of tumours, the spleen seemed to offer resistance to tumour formation, and there must be some good reason for this if it could be found; but in his own experience malignant tumour growth had occurred in two patients in whom splenectomy had been previously carried out.

CLASSIFICATION OF DISEASES OF THE SPLEEN

The lecturer reserved to his third and concluding lecture the discussion of diseases of the spleen, but he gave in his second lecture what he called a reasonable classification of such diseases, as follows:

1. Abnormalities, congenital or acquired.
2. Infections—acute, granulomatous, and parasitic.
3. Diseases affecting the myeloid and lymphatic elements.
4. Diseases affecting the reticulo-endothelial elements.
5. Diseases affecting the vascular system.
6. Tumours, simple and malignant—primary and metastatic.
7. Combined diseases of the spleen, liver, and haemopoietic system (Eppinger's "Hepato-lienalen Erkrankungen" and splenomegaly in hepatic cirrhosis).

The classification had to be based on pathology, as there was a long way yet to be traversed before these diseases could be accurately differentiated by clinical methods. The last group had been the subject of most elaborate investigation in Germany; it included diseases in which there were obvious interrelations between the liver, spleen, and bone marrow.

In closing this lecture, Dr. McNee referred to some of the abnormalities of the spleen. The spleen might be completely absent, or very many small spleniculi might be scattered throughout the abdomen. A point of importance was the lobularity of the human spleen. The division of the spleen into five, six, or seven separate lobes had frequently been described. "Floating spleen" or dislocation of the spleen was a well-known deformity, and of definite importance in abdominal diagnosis. The clinical detection of floating spleen might be quite simple or excessively difficult. Perisplenitis was a complication of very many splenic diseases, and the presence of acute, well-marked perisplenitis was often overlooked. Splenic infarction was extremely common, and splenic enlargement in fevers had to be considered, as also cysts of the spleen, especially haemorrhagic cysts, which were interesting and of surgical importance.

DISEASES OF THE SPLEEN

In his third lecture, delivered on March 4th, Dr. McNee dealt first with diseases affecting the myeloid and lymphatic structures. Myeloid metaplasia, he believed, was a "throw back" to the original function of the foetal spleen as a blood-forming organ. It occurred in a variety of diseases, such as pernicious anaemia, and splenic enlargement ensued. Apart from the lymphatic leukaemias, there appeared to be no special disease in which the Malpighian bodies were essentially involved.

Diseases affecting the endothelial elements (reticulo-endothelial system) were a very mixed group, including a considerable proportion of the splenomegalies of unknown and uncertain origin. Three types of splenic disease which might be classified as belonging to this group were: (1) chronic haemolytic (acholuric) jaundice; (2) disturbances in the lipoid metabolism of the reticulo-endothelial cells; (3) chronic splenomegalies of unknown origin, showing marked proliferation of the reticulo-endothelial cells and associated with giant cells. The first of these was such a well-known disease that it seemed unnecessary to refer to its clinical aspects. The spleens were seldom enormously enlarged, and they had a characteristic histological structure quite unlike that of any other form of splenomegaly. The second type of splenic disease mentioned was particularly interesting and puzzling, and it was possible that fresh study of the relations of the normal spleen to fat metabolism might help in its elucidation. This sub-group included Gaucher's disease, Niemann's disease, and hypercholesterolaemic splenomegaly in diabetes. In the liver the proliferation of the endothelial cells con-

taining the lipoid might, in any of the cases of the group, be so extreme that necrosis of liver cells and subsequent cirrhosis ensued. In bone marrow there might be an invasion of collections of these cells, giving an appearance resembling tumour formation. With regard to the third type several of the largest spleens in his experience fell into this category. He could do little more than describe the histology ; he had no good explanation to offer. The condition might be a response of the reticulo-endothelial cells to chronic inflammation of long standing. In several cases of this kind the liver was definitely cirrhotic, but in others he had no information about the liver, so that the question must remain open. The histological changes consisted essentially of a great proliferation of the endothelial cells, so that the spleen became a heavy solid organ and the pulp spaces and venous sinuses were encroached upon and partly obliterated. Along with this striking histological alteration, giant cells appeared, and were sometimes so numerous that the sections almost resembled those from a case of myeloid sarcoma.

Diseases affecting the vascular system formed the largest group of splenomegalies met with in Great Britain. The lecturer described two types of splenomegaly in this group: (1) one in which thrombosis had occurred in the splenic or in the portal vein ; (2) one associated with peri-ellipsoidal haemorrhages and nodular siderosis. In cases of the first type the splenic enlargement might be enormous ; one of these spleens was the largest he had seen, weighing over 9 lb. Microscopically the spleens showed nothing so characteristic histologically as to be of diagnostic value, and the chief feature made out was the hypertrophy of the spleen pulp associated with generalized fibrosis. In these cases perisplenitis and adhesions were particularly dense, creating unusual difficulties for the surgeon. In the second type the characteristic lesion, the siderotic nodule, had been observed in a considerable variety of conditions in which the spleen was diseased. It was one of the commonest findings in chronic splenomegalies examined in this country, and was recognizable at once whenever the enlarged spleen was incised. He had paid particular attention to the mode of origin of the nodules and their early stages of development. He was satisfied that the ring-like haemorrhages surrounding the arterioles were an early stage of the lesion, and that the haemorrhage underwent the ordinary process of fibrosis and organization. Both the fibrotic nodules and the perivascular haemorrhages surrounded arterioles of the finest calibre, and the vessel wall generally showed definite hyaline change. On attempting to trace the arterioles involved he was at first unable to account for their apparent abrupt ending in the pulp, until he learned the peculiar structure and functions of the ellipsoids. It was at or about the termination of the pencillar arteriole in the ellipsoid that both the fibrotic nodules and the haemorrhages were found, although the haemorrhage frequently ran back for some distance in the periarterial sheath. When the valvular function of the ellipsoid, preventing any flow-back of venous blood into the arterioles, was remembered, it seemed reasonable to suppose that in conditions of high portal blood pressure or of actual obstruction in the portal venous system a break or rupture was most likely to occur close to the obstructing valve. This was the type of case claimed by A. G. Gibson and a number of French writers to be of mycotic origin (splenic mycosis), but Dr. McNee himself was opposed to this view.

The lecturer touched slightly on spleen tumours. Simple tumours were very rare ; primary malignant tumours were also rare, and when they occurred they were always sarcomas. It was almost certain that primary carcinoma of the spleen did not exist.

Prognosis of most types of chronic splenomegaly met with in this country was, on the whole, unfavourable to prolonged life. The exception to this was chronic haemolytic (acholuric) jaundice, but even in this disease the patient had to run the gauntlet of a number of complications, such as gall-stones and biliary colic. Splenomegaly patients usually died from complications, and of these the most dreaded, but difficult to recognize in its early stages, was hepatic cirrhosis. Other complications to be feared were haematemesis, abdominal thrombosis, and the onset of the " haemorrhagic diathesis."

THE OPERATION OF SPLENECTOMY

In certain cases, such as Gaucher's disease, if the exact diagnosis was known beforehand, it would be inadvisable to remove the spleen, but, on the whole, the cases of splenomegaly in which the removal of the organ offered the best hope of cure far outnumbered the others. Splenectomy might be successful even in most desperate and unpromising cases. Certain precautionary measures were necessary before operation was considered. The first was concerned with the degree of anaemia present. If anaemia was at all pronounced, he believed in blood transfusion being done before, during, or after operation. Another necessary precaution was blood platelet counts before and after splenectomy.

In one group of cases *x*-ray treatment offered a promising alternative to splenectomy—namely, the chronic leukaemias, especially of the spleno-medullary type. Methods of treating these by *x* rays had improved of recent years, and he had two cases under his care at present in which the outcome so far as prolongation of life and return to good health were concerned could only be described as amazing. The chief danger from *x* rays was undue destruction of the leucocytic tissues, so that marked leucopenia resulted, and septic complications might ensue. Ligature of the main splenic artery was a method which, with the help of his surgical colleagues, he much desired to test in suitable cases of chronic splenomegaly. So far he had no personal experiences to relate, but the operation was apparently quite safe ; it was by no means a new suggestion. He could think of several types of cases in which this simpler operation might have been performed instead of splenectomy, and certainly this procedure should be seriously considered when dense and extensive retrosplenic adhesions greatly increased the surgical risks of removal.

LONDON COUNTY HOSPITALS MEDICAL STAFF

NEW SCALES OF SALARIES AND CONDITIONS OF SERVICE

At the meeting of the London County Council on March 3rd, the Central Public Health Committee brought forward the long-awaited proposals concerning the new scales of salaries and the conditions of service, to be adopted uniformly as from April 1st, for the medical staffs in the hospitals and institutions recently transferred to the Council from the Metropolitan Asylums Board and from the boards of guardians. Existing officers who are transferred officers within the meaning of the Local Government Act, provided they accept the conditions (with the exception of those relating to the period of probationary service), are to be given the option of being placed on the new scales. No comment has been made by the London Voluntary Hospitals Committee, to which these proposals have been submitted.

Grading of Staff

When the London County Council took over the hospitals the remuneration and conditions of service in the special hospitals hitherto controlled by the Metropolitan Asylums Board were, generally speaking, standardized, but no such uniformity existed at the general

hospitals under the control of the boards of guardians. A substantial part of the income of many of the medical superintendents of the latter has been derived from fees which have fluctuated from year to year. The conditions also varied widely as between the different hospitals in respect of number of beds, responsibility of the officers, and employment of consultants and specialists. The Central Public Health Committee admits that the last is an important question, but beyond expressing the view that the services of consultant staff should be freely available for patients in the hospitals, it suggests no definite policy as to the best method of employment of such staff; the matter will be considered next year.

It is thought desirable that every general hospital should have on its permanent staff, in addition to the medical superintendent, and according to the size of the hospital, one or more whole-time medical officers with special qualifications in medicine, surgery, or obstetrics, when necessary. These officers should be graded as senior assistant medical officers, and at the larger hospitals one of them should rank as deputy medical superintendent. Next in rank should be assistant medical officers, and subordinate to them house-physicians, house-surgeons, and clinical assistants. These last, consisting of recently qualified men and women appointed for limited periods, have, says the committee, performed valuable work by assisting the senior staff in routine matters, and in undertaking minor work independently. It is anticipated that some of them, after holding these residential posts for six months to two years, will begin private practice or take appointments elsewhere, while others will continue in the Council's service as assistant medical officers. For the post of senior assistant medical officer at a general hospital preference is to be given, in the case of surgical officers, to candidates who are Fellows of a Royal College of Surgeons or who are Masters of Surgery; in the case of medical officers, to Members of a Royal College of Physicians or Doctors of Medicine; in the case of obstetric officers, to candidates holding a high qualification, together with special experience, in obstetrical work. For officers at special hospitals generally, consideration will be given to those who have qualifications suitable for the particular branch of work. Assistant medical officers will have to be qualified medical practitioners of at least one year's standing, and they must have held a residential post for at least six months in a general hospital. The conditions of appointment of assistant medical officers are that there is a period of probation of one year, and at the end of four years' service the appointment is terminated unless the holder has applied for admission to, and been accepted for, a promotion list containing the names of those awaiting vacancies for the grade of senior assistant medical officer. The above grading is suggested not only for the general hospitals, but for most of the special hospitals under the Council's control, except that appointments as house-physicians, house-surgeons, and clinical assistants are not likely to be available at all the special hospitals.

Medical Superintendents

Formerly the medical superintendents of the guardians' hospitals received from £1,100 to £1,700 a year; this included fees earned and also cash values assigned for superannuation purposes to emoluments. The medical superintendents under the Asylums Board had a similar scale of salary, and their emoluments included an unfurnished house. Further, although the London County Council Regulations provide that fees received by its employees shall be paid into a county fund, it is held that in the case of medical superintendents certain exceptions may be allowed. These include fees received by doctors for acting as examiners—for example, for the General Nursing Council—for giving instruction to medical students, for various classes and lectures, and for literary work; the authority, however, of the medical officer of health should in all cases be obtained before any remunerated work of any character is undertaken. It is proposed that additional leave with pay, not exceeding one week in each year, be granted to medical superintendents and other whole-time medical officers when they act as examiners to outside authorities. The only emolument proposed for medical superintendents is an unfurnished house or quarters, valued at £100 a year for superannuation purposes. The salary scales proposed are as follows:

General hospitals	£900 to £1,550
Convalescent hospitals... ...	£900 to £1,100
Fever hospitals	£900 to £1,450
Tuberculosis institutions ...	£900 to £1,200
Children's hospitals	£950 to £1,650

Of the general hospitals, only two (with 265 and 320 beds respectively) will have a commencing salary of £900, rising to £1,150; and at the other end of the scale two (with 843 and 944 beds respectively) will have attached salaries of £1,300, rising to £1,550. In the intermediate cases the commencing and maximum salaries vary directly with the number of beds. In the fever hospitals the lowest scale is at the South-Western Hospital (323 beds, £900 to £1,150), and the highest at the river hospitals, where small-pox cases are concentrated (1,931 beds, £1,200 to £1,450, together with a special allowance to be fixed from time to time during epidemic outbreaks of small-pox). It is added that, as the amount of district medical work supervised by medical superintendents varies considerably, and in view of the possibility of all medical superintendents being ultimately made responsible for this work, they should, as part of the terms of their appointments, be required to supervise any district medical work allotted to them without additional remuneration, with the proviso that special consideration will be given to any case in which these added duties are exceptionally heavy. Wherever possible medical superintendents must reside within the curtilage of the hospital, otherwise a house will be provided by the Council as near as possible. The annual leave is to be six weeks, and the period of notice required is three months on either side.

Subordinate Medical Staff

It is proposed that deputy medical superintendents be employed only where beds exceed 600, and that two grades (with salaries ranging from £600 to £800 a year) be formed on the basis of beds provided. Two grades of senior assistant medical officer are suggested, with salaries ranging from £500 to £600; the higher grade includes those officers acting as deputy medical superintendents at hospitals of 600 beds and under, except at the smallest hospitals. For the grade of assistant medical officer, the scale of salary is from £350 to £425. If the engagement is extended beyond four years, the minimum is to be increased to £450 a year. It is proposed that house-physicians and house-surgeons (resident) and clinical assistants (non-resident) be engaged for strictly limited periods and receive £80 to £100 a year respectively, with no emoluments, but with meals when on duty. Generally speaking, all assistant medical officers are to be resident, but departures from this principle may be allowed if the interests of the service permit. For deputy medical superintendents and senior assistant and assistant medical officers, provision for periodic week-end leave is to be made; sick pay is to be allowed on the same scale as for medical superintendents, and annual leave and length of notice are to be fixed on the basis of the relative status of the grades concerned. House-physicians and house-surgeons are not to be regarded as employed in a whole-time capacity, and are to be granted reasonable off-duty time for study. Clinical assistants will attend for six sessions of about four hours' duration each week, and sick pay is to be granted on a basis similar to that allowed to part-time assistant medical officers on yearly engagements in the Public Health Department. It is proposed that the period of engagement of this grade of staff be limited to six months, with the possibility of extension for further periods of six months up to two years, provided that not more than twelve months are spent at any one hospital.

Those acting as locumtenents will receive a provisional maximum rate of remuneration of seven guineas a week, plus emoluments. If there is no accommodation in the

hospital for such officers, it is considered that an additional payment at the rate of one guinea a week should be made in order that they may rent rooms in the vicinity. With regard to visiting medical officers at small hospitals and homes, the rates of remuneration are laid down as £300 a year for an average attendance of between one and a half and two hours a day, and £200 a year for an average attendance of one hour a day. The additional expenditure involved in these proposals is £8,689 in the first year, and the cost in subsequent years is estimated at an average of £5,744.

THE COUNTY HOSPITAL SERVICES OF LONDON

FIRST YEAR'S EXPERIENCE OF L.C.C. ADMINISTRATION

The Central Public Health Committee presented to the London County Council on February 24th a report on the administration of the transferred hospital services for the period beginning April 1st, 1930, when the Council became responsible for those services under the Local Government Act.

It will be remembered that, under that Act, central direction through a committee of the Council was substituted for the individual direction of twenty-six separate authorities—the Metropolitan Asylums Board and the various boards of guardians—and the responsibility, in the main, for the services was placed upon the county medical officer of health. The committee's report stated that the central co-ordinating control was exercised through seven subcommittees, to which considerable powers had been delegated. A subcommittee had also been appointed for each hospital or institution, except in a few cases in which it was convenient to include two or more establishments under one subcommittee. The total membership of the existing seventy-two subcommittees, including these hospital committees, was 549. Some members were on more than one subcommittee, and the actual number of members was 382, of whom 360 were co-opted members. In appointing these members it was possible to secure, in the majority of cases, the services of former members of the late authorities, and the assistance rendered to the Council by this large body of devoted men and women during a year of great pressure was gratefully recognized.

Transferred Institutions

The total number of transferred hospitals and institutions was seventy-six, with 41,984 beds. To show the magnitude of the service represented, it might be stated that, while there were about one hundred voluntary hospitals in the County of London, their total accommodation was only about 14,000 beds. The management of the thirty-three hospitals transferred from the Metropolitan Asylums Board had for many years been under the unified control of a central authority, and the service which they had rendered had been administered as one entity. The arrangements generally in force under the Board's regime had been continued. With regard to the hospitals and institutions under the control of the guardians, the position was naturally very different, owing to the fact that they had been managed by twenty-five separate authorities. The hospitals included some for the acute cases and others for the chronic cases, the latter comprising mainly incurable diseases of senility and other chronic affections. A question to which the committee had given consideration during the year was whether it was advisable to have hospitals reserved entirely for those acutely ill and others for the chronic. There was some opinion that this was a desirable arrangement, but experience had shown that it had serious disadvantages. The most important was that it was not possible to secure the same standard of medical and nursing care in an institution containing only patients of the chronic type as in a hospital in which a variety of cases, including the curable, were treated. In the interests of both patients and staff it was considered that the best arrangement was to aim at having hospitals in which both the acute and the chronic cases were accommodated, in the proportion of about three to one. The attainment of this end would take some time.

Co-operation with Teaching Hospitals

On the matter of conference with representatives of the voluntary hospitals, as laid down under Section 13 of the Local Government Act, the report stated that the Voluntary Hospitals Committee had been consulted already on proposals for uniform scales of salary and conditions of service for medical, nursing, laboratory, and other staffs. Questions concerning medical education, particularly those referring to medical instruction in obstetrics and consultant services, had also been discussed at the meetings between the representatives. The representatives of the voluntary hospitals desired that, if the provision in their institutions (with financial support from the local authorities) of the extra obstetric beds needed by the teaching schools was not practicable, obstetric cases in the municipal hospitals should be made available for the teaching of students. Existing maternity units in the Council's general hospitals were not large enough to be suitable for teaching purposes, and were fully used for the training of nurses. Acquiescence was expressed, on the Council's behalf, to the principle of allowing the teaching of students in connexion with the Council's maternity beds as and when satisfactory arrangements could be made and suitable units were available. The Council's hospitals contained types of chronic disease rarely seen in voluntary hospitals, and it was stated that it had been agreed that facilities should be provided, as far as possible, for the medical education of students and post-graduates at these institutions.

The scheme of laboratory services which the Council has in hand provides for the establishment of five group laboratories, suitably located, capable of dealing with the more specialized pathological work. The first of these group laboratories will be ready to function in April, and all of them are expected to be available before the end of the year. The report stated that at the other general hospitals steps were being taken to bring the laboratory services up to a suitable standard.

Questions of Staffing

The Central Public Health Committee has been largely occupied during the year with the scales of salary and conditions of employment of the staffs of the transferred hospitals and ambulance services, who number nearly 19,000. The position has been complicated by numerous questions of difficulty with superannuation and pension conditions, tenure, and other rights and privileges. The nursing staff, numbering about 10,000, was most urgently in need of consideration. Provisional proposals for new scales were prepared, and the immense task of applying the scales individually to the members of the staff concerned, and of adjusting each officer's appropriate position on the new scales, was being proceeded with as far as possible. The shortage of candidates for the nursing profession had been felt in the public hospitals of London, and recently it had been agreed to increase the normal nursing staff by 500 nurses. The question of the medical staff was next dealt with, and, having regard to the needs of the service, the same careful and prolonged consideration had been given to the subject of appropriate scales and conditions. The committee hopes to be in a position to submit proposals regarding the medical staff at an early date.

Finally, there is a note on the ambulance service, which now includes two divisions—a general section and an accident section. The number of ambulances attached to the fourteen accident stations is 23, and to the six general stations, 160. The number of calls dealt with at the accident stations during 1930 was 43,930, and the number of persons removed by the ambulances attached to the general stations was 200,481. The 183 ambulances travelled a total of 1,617,950 miles.

ATMOSPHERIC POLLUTION

REPORT OF SCIENTIFIC INVESTIGATIONS

The issue by the Department of Scientific and Industrial Research of the sixteenth report for the year ended March 31st, 1930, on the investigation of atmospheric pollution[1] calls attention again to the existence of the smoke problem, and the extent to which attempts to solve it are meeting with success.

As from April 1st, 1927, the Department, at the request of a number of local authorities, undertook responsibility for co-ordinating the observations of atmospheric pollution which for some years have been made by local authorities and other bodies, and for seeing to the conduct of research into the nature of pollution and the best way of measuring it. The cost of this work is met by contributions from co-operating bodies, supplemented by a grant from the Department. The Department has appointed an Atmospheric Pollution Research Committee to advise on the work, and in order to maintain touch between the central organization and the co-operating authorities, and to promote the application of the results of the research, an autonomous body known as the Standing Conference of Co-operating Bodies has been established. Reports by the Standing Conference and the Research Committee are included in the document now under notice, as well as a report by the superintendent of observations, Dr. J. S. Owens.

The Standing Conference mentions that in the year of report, 1929–30, it caused inquiries to be made among the co-operating authorities as to steps they had taken to abate the smoke nuisance, since it was felt that knowledge of action taken and experience gained by different authorities might be useful to others. The summary of the replies given in the report indicates that, apart from the powers given to them under the Public Health (Smoke Abatement) Act of 1926, a number of authorities are taking active steps by enlisting the co-operation of house dwellers and factory owners in their efforts to solve the domestic smoke and factory smoke problems. Domestic smoke is now well recognized to be the principal contributory cause of the smoke nuisance in many of our large towns. Estimates for London and Glasgow have shown that smoke in these cities is 2½ domestic to 1 industrial and 3½ domestic to 1 industrial respectively. The burning of every ton of raw coal in a domestic open grate has been estimated to cause as much as ten shillings' worth of damage in many areas. Evidently the town dweller must sacrifice his cheerful coal fire if he is to gain the benefit of a clear atmosphere, and many local authorities, the report indicates, are doing what they can to induce this spirit of self-sacrifice. As regards smoke from industrial furnaces or public premises, the summary refers by way of example to steps taken by Wakefield, Dewsbury, Glasgow, Sheffield, and Edinburgh.

The Research Committee in its report describes a new investigation. That smoke from densely populated districts affects the clearness of the atmosphere throughout wide areas is shown by the fact that visibility at Valentia, on the south-west of Ireland, has been found to be affected by smoke from industrial areas 350 miles away. The committee has set out to get more information about the spread of pollution by an investigation in progress at Norwich, in which daily observations are made of the spread of pollution down wind from the city. The committee refers also to the development of an apparatus, a description of which is about to be issued, for measuring sulphur, the most actively destructive element of pollution in the air. The importance of sulphur measurement may be illustrated by reference to the various estimates of the damage caused to buildings by that element of pollution, the most recent being by Sir Frank Baines, who concluded that in the last twenty-five years sulphur has caused damage to buildings to the extent of £55,000,000 to £60,000,000. The apparatus has been designed to be simple in operation and suitable for routine measurements.

[1] London: H.M. Stationery Office. 1931. (4s. net.)

A comparison of the annual records of pollution from 1915 to 1928 indicated that, while there was a progressive improvement down to 1921–22, little advance had been made since. But the year 1929–30, according to Dr. Owens, marked the beginning of a trend in the right direction. Nevertheless, his report adds further evidence, if it be needed, of the loss of daylight and of ultra-violet light attributable solely to smoke. Records of ultra-violet light taken at Sheffield show that in November and December of 1929 no ultra-violet light at all was received in the middle of the city. The question of ultra-violet light is also discussed in an appendix dealing with Rochdale, contributed by Dr. J. R. Ashworth, which indicates that, even by comparison with a station only a mile away, the centre of Rochdale loses as much as 29 per cent. of ultra-violet light during the first half of the year.

[FROM OUR CORRESPONDENTS]

School of Public Health and Tropical Medicine in Sydney

The new School of Public Health and Tropical Medicine at the University of Sydney has passed through its first year with considerable success. The activities of the school include not only instruction and research in tropical medicine and public health, but also special education in school and building hygiene. Altogether 158 students attended during the year. Of these, 9 were medical graduates, 39 were medical undergraduates, 11 were students of social hygiene, 9 were architectural students, and 90 were graduate school teachers. Three diplomas in tropical medicine and two in public health were granted. The course in tropical medicine occupies a period of three and a half months, and corresponds closely to those of London and Liverpool. The faculty of medicine in the university has recognized the importance of the school by appointing its director, Dr. Harvey Sutton, professor of preventive medicine. This is the first chair in Australia in this branch of medicine. A hookworm and filariasis survey of Norfolk Island was undertaken during the month of January, 1931, completing the hookworm survey of the Australian Commonwealth, Papua, and the Mandated Territory of New Guinea. This work which was conducted for a period by the Rockefeller Institute in collaboration with the Commonwealth Government, and has been carried on by the Commonwealth Health Department.

Royal Prince Alfred Hospital

During 1930 an association entitled "The Royal Prince Alfred Hospital Resident and Ex-Resident Medical Officers' Association" was founded in Sydney. It is composed of medical practitioners who are now, or who have been, members of the resident or honorary staff of the Royal Prince Alfred Hospital. As its objects it has the publication of a Royal Prince Alfred Hospital Year Book containing contributions from the staff of the hospital, and an annual reunion of members in educational and social activities. The first reunion, held during October, 1930, was a pronounced success. A full week's programme of lectures and demonstrations was carried out by the members of the honorary staff of the hospital. The week concluded with surfing, a golf tournament, and the first annual dinner of the association at the Elanora Country Club. At this first reunion each section of the hospital staff was allotted a period for the demonstration of its work. At future meetings certain sections will be chosen in order that more detailed instruction in various subjects may be possible.

Victorian Council for Mental Hygiene

A meeting convened to form a Victorian council for mental hygiene was held at the Medical Society Hall, East Melbourne, with Sir Richard Stawell in the chair. Dr. S. V. Sewell said that the committee of the Neurology and Psychiatry Section of the Victorian Branch of the British Medical Association, who had called the meeting, had recognized, especially since the war, that a very large number of the nervous disturbances from which patients who consulted doctors were suffering was due to the fact that the patients were "misfits," and that conditions with which they were constantly confronted were due to the fact that they did not choose their work in life satisfactorily. Councils for mental hygiene had therefore been formed in many countries, and were doing magnificent work. It was realized that they could only be successful if there was adequate co-operation between the medical profession, the teaching profession, and all social workers. Professor W. S. Dawson said that, until recently, the whole subject of mental disorder had been limited to the treatment of those in mental hospitals; there had been very little organized attempt to do much for patients before they reached the stage at which they had to be certified. There was now a very much wider conception of mental trouble. This was an age of prevention, but patients were seen by specialists far too late, and their condition was often the culmination of a long series of maladjustments, which could sometimes be traced back to the years of adolescence or even of childhood. Psychiatrists realized the importance of dealing with children with nervous symptoms. The various fears, emotional upsets, and feelings of inferiority and insufficiency, if fully dealt with at an early age, could be contended with and would give place to a feeling of self-confidence. There was a time in the life of many a hardened criminal when he was a decent law-abiding youth, and then through some unfortunate environmental factor or some incident in his life he had turned to the path of antisocial behaviour. Mental hygiene was attempting to introduce preventive measures for such cases. The parental and home influence was of immense importance. Vocational guidance was of great value to the boy who was leaving school; by it he might be definitely advised for what type of occupation he was best suited. There was also the enormous question of mental deficiency. Children who were two or three years mentally retarded should be given special types of training. There had been far too much pessimism in the attitude towards defectives; with patience, and with special facilities, many of them could become useful in the community. Professor J. A. Gunn looked forward to the time when there would be closer co-operation between the educationists, the medical profession, and the social workers, each of whom saw the problem from his own particular angle. He thought that the meeting was a historic occasion for the city of Melbourne, in that it was highly representative of the different orders and associations. Mr. V. McRae said that the fatalistic view of the future of the mentally incapable was not justified by his experience. The Education Department had long been endeavouring to do something for mentally defective children, and had found that if the right classification could only be obtained early enough it meant a very great deal in the child's future progress. Dr. Vera Scantlebury stressed the importance of teaching the mother and those dealing with the child not to overstimulate or to over-fatigue him. Careful attention to nutrition would do very much to prevent a number of mental disorders. A resolution was proposed by Mr. Frank Tate "That this meeting constitutes itself as the Victorian Council for Mental Hygiene, and that application be made for affiliation with the National Council for Mental Hygiene in Great Britain," and this was carried unanimously.

University of Melbourne

The number of first-year medical students has now passed the pre-war figure. Arrangements have been made for greater teaching facilities in organic chemistry during the first year of the medical course. It has also been decided to institute diplomas in ophthalmology and oto-rhino-laryngology. It is announced that in future the examinations for the degree of M.D. and M.S. will be held half-yearly—in March and in September.

Australian Medicine in the War

The first volume of *The Official History of the Australian Army Medical Services, 1914–18*, has been published. This work, the compilation of which has been arranged by the Commonwealth Government, has been edited by Colonel A. Graham Butler, D.S.O., V.D.

India

Treatment of Rabies

Reports on the use of Sir David Semple's antirabic vaccine have been received from the King Edward VII Memorial Pasteur Institute, Shillong, and the Pasteur Institute of Southern India at Coonoor. In the thirteenth annual report of the first-named institution, for 1929, it is announced that during that year this form of treatment was made available at distant centres throughout Assam to an extent which materially altered the conditions under which antirabic measures in that province had been previously carried on. In 1917, when the Shillong Institute was opened, 569 cases were treated, with 5 deaths (0.88 per cent.) and 4 failures (0.71 per cent.); in 1929 there were treated 1,110 cases, with 7 deaths (0.63 per cent.) and 5 failures (0.45 per cent.). The Semple vaccine is first prepared as a 2 per cent. emulsion of fixed virus in normal saline solution containing 1 per cent. carbolic acid. After being kept at 37° C. for twenty-four hours, the vaccine is diluted with an equal volume of normal saline solution, is tested for sterility, is put up in single-dose ampoules, each containing 5 c.cm., and is then again tested for sterility. The vaccine is stored at 4° C. for at least three weeks before it is issued. Each centre is supplied with twenty-eight doses, enough for two full treatments. As soon as one or more cases arrive for treatment anywhere, the appropriate series of doses are requisitioned by telegram and are dispatched at once. Unused vaccine four months old is replaced by a fresh supply. Lieut.-Colonel J. Morison, I.M.S., director of the Shillong Institute, reports that this system has worked well. One case of paralysis after treatment is reported in a European; the patient recovered completely after a fortnight in bed, during which he was given massage and passive movements. This is the first case of the kind at the Institute, where 18,234 patients have already been treated by this particular vaccine. The vaccine was injected intravenously in 2 c.cm. doses on alternate days in twelve cases of severe biting by animals (proved to have been rabid by the finding of the Negri bodies or the presence of undoubted symptoms); there were no deaths. The extension of this most effective treatment, by arranging for it to be given without delay in outlying districts in Assam, will undoubtedly diminish the mortality from rabies. During ten months of 1929 there were treated at the Coonoor Institute 607 patients, an increase of 242 on the number dealt with in the previous twelve months. This is

ccounted for by the fact that about the middle of 1929 here was a serious outbreak of rabies in Ootacamund nd several rural areas in the Nilgiris, due to widespread ackal infection. Coonoor and its suburbs were not ffected by this incidence. Many instances occurred of ackals rushing along the highroads and into villages and ouses, where they attacked human beings indiscriminately, causing a grave scare. Semple's vaccine was used throughout the year under review, and Major K. R. K. Iyengar, I.M.S., director of the Coonoor Institute, remarks that three months is considered to be the limit of its efficiency. He advises daily doses of 5 c.cm. of the 1 per cent. emulsion, irrespective of whether the cases are considered light or severe. No instances of paralysis were encountered.

Infant Mortality in the Central Provinces

Attention is called in the annual public health report for 1929 of the Central Provinces and Berar to the very high infant mortality, which rose to 240.49 per 1,000, as compared with 238.41 in the previous year, and is the highest in India. The mortality figure for the age-period up to 5 years is even worse, and 53.93 per cent. of the total deaths occurred in children in this group. Major C. M. Ganapathy, I.M.S., Director of Public Health, attributes this deplorable state of affairs to poverty, ignorance, overcrowding, and bad housing conditions, and he regrets that there are signs of apathy towards the National Baby Week celebrations in several towns, including Jubbulpore. He appeals for more assistance in obtaining supplies of milk for necessitous mothers and children, and considers that the existing welfare centres might well be used for distribution purposes. Many more of these centres are urgently needed in the towns and also in rural areas, but the money for their establishment is lacking. Skilled attention at childbirth is another requirement, and home visiting generally is handicapped by shortage of staff; hospitals for infants would be immensely useful, and much remains to be done in the way of securing ante-natal treatment and advice for expectant mothers. The Indian Red Cross Society is devoting itself energetically to providing instruction for mothers in the care of infants, the treatment of infantile diseases, and improvement in the conditions of childbirth. The Government has been unable to find the increased financial support which is desired, and may even have to reduce its grants, but it is suggested that if the bulk of the educated population realized the extent of the evil, and the ways in which its reduction could be brought about, a great deal could be done without much sacrifice. Improvement in the general sanitary conditions is very slow, there being unwillingness to enforce local by-laws in spite of the high incidence of fevers, respiratory diseases, dysentery, and typhoid fever. The opinion is expressed that more energetic action in this direction would have an appreciable effect on the infant and child mortality.

Improvements in Mental Hospitals

In the three years 1927 to 1929 there was a steady daily average increase in the number of patients in the Punjab Mental Hospital at Lahore, the figure rising from 889 in the first year to 949 in the second, and to 1,010 in the third. The death rate has fallen, however. The receipts from paying patients have grown larger, and the costs of administration have been decreased, despite necessary additions to the staff. A female hospital block has now been added, designed on modern lines, and capable of undertaking all the kinds of treatment likely to be necessary. During the same triennium there was a similar fall in the death rate in the Agra and Benares mental hospitals; in the second of these the improvement is attributed partly to the construction of a better water supply, and partly to the fact that this institution now receives only criminal lunatics, and has, therefore, a population that is generally more intelligent and of better physique than the non-criminal lunatics. In the mental hospital in Nagpur special measures have been introduced for the systematic search for, and elimination of, focal sepsis in every patient; this, it is hoped, will diminish the time spent in hospital, and increase the number of discharges. The effect of these steps on the hospital statistics will be watched carefully. There are three mental hospitals in the Presidency of Madras, and the medical superintendents of these met in conference in 1929. They subsequently formulated schemes devised to bring their respective institutions more up to date as regards the provision of facilities for curative treatment, including occupational therapy. The health of the patients in the Provincial Mental Hospital in Assam having been unsatisfactory in previous years, rebuilding operations were undertaken, and as a result of the better accommodation now becoming available, there is already a marked improvement.

Scotland

Glasgow Maternity Hospital

The annual meeting of the Glasgow Royal Maternity and Women's Hospital was held on February 26th, under the presidency of Lord Provost Kelly. Commenting on the report for the year Professor Bryce said that the maternity services had expanded in the most striking manner as a result of the evolution of medical services under the Department of Health. About 10,000 cases had been treated in the hospital during the past year—a large increase on the number of the previous year. Applications for treatment had either been granted or arrangements had been made for complete supervision at the patient's own home. This was a great achievement, and had been obtained through the co-operation of the public health authorities and the bodies grouped under the Public Assistance Committee. Referring to progress in research in this department of medicine, Professor Bryce quoted the conclusion reached by the Departmental Committee on Maternal Mortality, which insisted that the solution of the complex problem of maternal morbidity and mortality would be found in an increased watchfulness at all stages of pregnancy and labour, rather than in any single, arresting, or comprehensive remedy.

West Govan Child Welfare Association

At the twelfth annual meeting of the West Govan Child Welfare Association Dr. J. Parlane Kinloch, Chief Medical Officer of the Department of Health for Scotland, said that society at the present day was in much the same position as it had been after the Napoleonic wars. Indebtedness bore the same relation to national wealth and resources, but a century ago Britain had emerged triumphant. At the present day new opportunities had got to be made, and it was from the development, not of old industries, but of new industries, that the prospect of success was going to come. The first requisite to-day, he thought, was an adequate health service, and the best economy was that of health. The progress achieved in safeguarding the health of the people might be gathered from the fact that while the average duration of life in the sixteenth century was only twenty years owing to the enormous death rate of young children, and while at the end of the eighteenth century it had

been raised to only twenty-five years, the average duration of life in Scotland to-day was fifty-seven years. They had the power now of making valuable experiments in social welfare. Lady Helen Graham explained that the characteristic of this association was an alliance between voluntary and municipal effort, for there was a tendency nowadays to accept what the State provided without further effort; the best results, she said, could be achieved only by personal enthusiasm and by the voluntary spirit. Dr. A. S. M. Macgregor, M.O.H. for Glasgow, said that he was convinced that the best work in child welfare was done by a combination of voluntary and official effort. The amount of ante-natal work carried on in Glasgow was indicated by the fact that during the past year in no fewer than 50 per cent. of the births the mothers had attended the ante-natal clinics that were provided.

Red Cross Society

The annual meeting of the City of Edinburgh Branch of the British Red Cross Society was held on February 24th, with Sir David Wallace, F.R.C.S., in the chair. Colonel Mackenzie, D.D.M.S., Scottish Command, said that the military hospital at Edinburgh Castle was unsatisfactory, and that the War Office had regarded with favour a proposal to build a new hospital at Redford, where the Edinburgh garrison was stationed. The report for the past year stated that voluntary aid detachments in Edinburgh county comprised 268 members, of whom 120 were mobile. Probationers undergoing training numbered 48—a larger number than that of the previous year. The report also mentions that a team from Edinburgh, No. 8 Detachment, won the Stanley Shield in London last May, a trophy open to teams from the whole of Great Britain. This is the third time that an Edinburgh team had been successful in winning the all-British trophy. It was pointed out by the chairman that mobile members of voluntary aid detachments might be regarded as the nursing reserve of the Navy, Army, and Air Force.

Royal Edinburgh Mental Hospital

The annual meeting of the Royal Edinburgh Hospital for Mental and Nervous Disorders was held in the City Chambers, Edinburgh, on February 23rd. Bailie Wilson M'Laren, who presided, said that this institution had taken a leading part in the remarkable progress that had been made during the last twenty-five years in the treatment of those who were sick in mind. The changes that have taken place in this period in the provision of treatment are referred to by Professor G. M. Robertson, physician superintendent, in his annual report for 1930. These changes, he suggests, might be summed up by the term "hospitalization." Twelve years ago efforts towards improvement were handicapped by the fact that they were entirely confined within the walls of the institutions. Mentally sick persons could not be admitted to mental hospitals unless they passed the severe legal test of certification. On sentimental grounds this had been objectionable, and on medical grounds it had been a barrier to early treatment. The trend of medical science to-day was towards early treatment and prevention. In psychological medicine an important principle was to begin treatment with the young, when the mind was plastic and when the first slight abnormalities could be noted. Within the mental hospital emphasis should be placed on voluntary treatment, since certification stood in the way of every attempt at early treatment. According to the report Edinburgh has probably a more compact and complete organization for dealing with mental disease than any other city in Great Britain. Apart from the social services, facilities for treatment include clinics for children and juveniles, mental out-patient departments, and the Jordanburn Nerve Hospital. In addition, the mental hospital is associated with the medical school. The report states that the managers of the Royal Edinburgh Mental Hospital have incurred considerable liabilities in perfecting these organizations. The Jordanburn Hospital for Nervous Diseases was provided by modernizing an old building at a cost of £20,000, and an out-patient department of this hospital cost £10,000. The endowment of a chair of psychiatry entailed an expenditure of £10,000, a lecture theatre £8,000, while £2,000 was spent in fitting up a clinic for the young. The mental hospital now consists of Craig House and West House. The fact that the majority of the patients come voluntarily to these institutions is attributed mainly to a realization by the public that mental patients, if suitably treated in time, may be expected to recover.

Edinburgh Clinic for Child Psychology

A new psychological clinic for children and juveniles, under the management of Edinburgh University, was opened on February 18th by the Marchioness of Linlithgow. The clinic, which is situated at Morningside Park, has been established in connexion with the Jordanburn Hospital for Nervous Diseases. Sir Thomas H. Holland, Principal of Edinburgh University, presided, and said that Dr. Drever, reader in psychology in Edinburgh University, had organized a remarkably successful school of psychology in this city, and that the University Court had felt justified in utilizing part of the Carnegie grant for the present year towards the foundation of a new chair in psychology. He added that the present-day asylums were maintained for the care of those who in the present state of knowledge had to be regarded as incurable, but it was now recognized that the most direct results were obtained by investigation among children. It was possible that cases of permanent insanity among adults were due to the ignorance of mothers, nurses, and school teachers, as much as to innate mental abnormality of the child itself. Neglect of the pre-school child and failure to regard asylums as laboratories rather than as cemeteries were matters which would strike a future generation as a definite indication of the mental abnormality of public authorities. In declaring the clinic open Lady Linlithgow said that no mother of a family could fail to be interested in the psychology of the child; its whole future depended on the way in which it was understood and brought up. A parallel might be drawn between the plant and the child. If a carefully tended plant withered, they immediately asked themselves what was the cause, and took endless trouble to find out. How much more did a child require such individual treatment! In the new clinic, where doctors would be able to work under the best conditions, the routine examination in each case would include a medical examination and a report from social workers. Dr. Drever stated that the clinic had been started six years ago to deal with delinquents, but it soon became clear that an earlier contact with behaviour problems was essential. Early danger signals could be recognized by an observant teacher better than by anyone else outside the home or family. The clinic would be open every afternoon, and there would be close co-operation between the psychiatrist and the Jordanburn Hospital, as well as co-operation with departments of child life and health, with the Sick Children's Hospital, and with the School of Social Study. They also hoped to be able to help medical educatic and to perform a social service to the community.

Correspondence

OBSTETRICAL EDUCATION OF THE UNDERGRADUATE

SIR,—Of all the world's obstetricians, no one's opinion is entitled to greater respect than that of Professor Essen-Möller. His expressed opinion (February 21st, p. 326) that a six months' course in practical obstetrics and gynaecology for British students would involve "wasting their time" must be faced at once. I venture to suggest that Professor Essen-Möller is not sufficiently aware of the exact conditions of British midwifery, and is therefore unable to contrast it with that of his own country.

The obstetric problem is different in the two countries. In Sweden a very large proportion of women (94 per cent. in Stockholm itself) are confined in hospitals under the close supervision of senior and junior whole-time specialists. In Britain the bulk of midwifery practice is domiciliary, and is in the hands of midwives. The general practitioner acts as a consultant to the midwives, and in many districts—especially the large urban centres—the tendency is for the midwife to call in the younger men. It is most desirable that these younger practitioners should be prepared for the responsibility by a much more extended training than is in force in the majority of British schools at the present moment. Especially is it necessary that they should have attended and witnessed a large number of natural labours before they enter upon general practice. It would be much more difficult to insist on additional training after qualification than to increase it whilst the student is under full control.

A comparison of the Swedish and British midwives makes this even more desirable. The course of training for midwives in Sweden lasts two years—twice as long as ours—and each pupil conducts eighty to one hundred deliveries—four to five times as many as do our pupil-midwives; for these and other reasons she is a much more highly trained woman than her British sister.

In Sweden the medical student's course in obstetrics and gynaecology lasts four months only, but he "lives in" all that time, is always under the close supervision of whole-time specialists, and he conducts forty to fifty deliveries. I do not care to confess how this contrasts with the present practical training in midwifery at many of our schools.

This is my answer to Professor Essen-Möller's criticism of a proposed six months' course for British students. There are other important arguments in favour of it, but, in my opinion, these are best discussed round the committee table.—I am, etc.,

Sheffield, Feb. 22nd. MILES H. PHILLIPS.

GENETIC RELATIONSHIP BETWEEN CRETINISM AND HYPOTHYROIDISM

SIR,—There seems to be a gap in our present knowledge as to the relative positions of thyroid deficiency and cretinism from the heredity point of view. The fact that the neuropsychic condition characteristic of congenital "cretinism" can be cured by the continued administration of thyroid extract shows that the delayed or inhibited functional activity of the cerebral neurons is not due to absence of these neural elements, the result of a germinal defect. The amentia in this case is secondary to the lack of thyroxine. But the problem of the nature of the defective thyroid development still remains.

Is this dependent on some loss of, or defect in, the genetic mechanism in the germ cells which controls the development of the thyroid gland during embryonic life, and, if so, is this defect transmitted to offspring (under certain conditions of mating) along Mendelian lines, or is it the outcome of injurious influences like lack of iodine acting on the germ plasm before fertilization, or during pre-natal life, as is thought by some to be the case in primary amentia? Certain facts, such as the occurrence of cretinism in one twin, the other being normal, seem to support the mutational rather than the environmental explanation. It might be possible to obtain some further light on this problem by a careful study of the thyroid development, and of the neuro-psychic state in the children (of the F_1 and later generations) of cretins, and other subjects of hypothyroidism of lesser degree, in whose cases, while the symptoms have been removed, the thyroid defect remains.

The interval of time since thyroid feeding began to be employed in such cases has now been long enough to provide some data of the patients who have married and have produced offspring. It would also be useful to consider cases of hyperthyroidism from this genetic point of view. Further information on this subject would be helpful both to medical science and to genetics.—I am, etc.,

Leicester, March 1st. C. J. BOND.

MORTALITY IN ACUTE APPENDICULAR DISEASE.

SIR,—I should like to comment on some of the excellent points made by Professor Wilkie in his paper published in the *Journal* of February 14th.

For several years I have taught acute appendicular obstruction (after Professor Wilkie's work) as a separate preliminary entity of acute appendicitis, and the outstanding points I have noticed are:

(*a*) The severity of the colicky pain; it doubles patients up, causing them to roll about. I have known two such cases in which the patients were sent to hospital as suffering from perforated duodenal ulcer. This restlessness is of diagnostic significance; it means mechanical pain, whereas a patient is almost always immobilized by an inflammatory pain. As inflammation supervenes, the patients gradually lie quiet and still.

(*b*) The pulse and temperature are close to the normal; this encourages waiting, and the application of the label of intestinal colic, especially if there is any suspicion of dietetic indiscretion.

(*c*) The retching or vomiting is repeated, whereas it is unusual for a patient with true acute appendicitis to vomit more than once or twice.

I entirely agree with Professor Wilkie on the great value of the time spent in "coaxing out" an appendix unruptured. Too frequently is the quality of a surgeon judged by the speed with which he performs standard operations and by the smallness of his incisions. Speed is a relic of the pre-anaesthetic days. It was Lord Moynihan, I think, who said that "the man who has one eye on the clock and the other on the abdomen is not a good surgeon," but he did later add the rider that most good surgeons are quick. A liberal incision and gentle patience, although lengthening the operation by several minutes, will shorten the patient's convalescence by days. Sometimes the short time of development and the tension in an obstructed appendix are surprising, and a catastrophe is precipitated if the rupture occurs in the abdomen before or during the operation.

Although I was brought up in the "open wound school" of Professor Wilkie, after reading Lord Lister's work I began to close my wounds accurately in infected cases, using No. 0 catgut. Each layer is gently and thoroughly cleansed with hot saline, flavine, or weak monsol solution, and exactly apposed by interrupted tensionless sutures and fitted snugly around the tube.

If possible, I cleanse more thoroughly the two layers of subcutaneous fat and obliterate their dead space with silkworm-gut sutures. I close the skin with Michel's clips. I think that the wound itself, after such a cleansing, can deal with any remaining infection, especially if no culture medium is left—for example, tissue strangulated by tight sutures. The accurate closing of the layers about the drain effectively prevents any reinfection from it; by the time the tube is disturbed (in thirty-six to forty-eight hours) there is sufficient plastic lymph around it to make the wound "watertight." In several hundred cases of acute appendicitis, using this method, I have had very few wound infections. Occasionally catgut ligatures have been shed from the subcutaneous blood vessels, and here I regard the cutting and coagulating diathermy of use in sealing these and obviating the necessity for ligatures.

To avoid post-operative ileus or obstruction in general peritonitis, I believe the following points to be all-important:

(*a*) Minimal use of morphine before and after the operation, replacing it by rectal paraldehyde (1 drachm to the stone of body weight) or similar drug.

(*b*) Placing of the incision over the infected site (by a split muscle or Battle) so that a clean area is not traversed as in the paramedian incision, and the careful avoidance of handling the ileum and small intestine.

(*c*) Post-operative application of the Ochsner conservative treatment of appendicitis, together with infrequent dressings and heat to the abdomen, but not by fomentations.

(*d*) Total avoidance of purgatives and drugs like pituitrin and eserine. I regard them as useless and dangerous. I begin with liquid paraffin, half an ounce twice daily immediately after the operation; distension and flatulence are eased by oil and turpentine enemas.

(*e*) Daily administration of intramuscular doses of anti-gas-gangrene serum until the gross pyrexia settles.

If ileus or obstruction should occur, repeated stomach washing with a small duodenal tube, the giving of turpentine enemas or the performance ultimately of a timely jejunostomy under local or spinal anaesthesia, after intravenous saline and glucose, will usually pull the patient through. Occasionally after the spinal anaesthetic, one hears the noisy evacuation of the bowels before the operation has begun.—I am, etc.,

London, W.1, Feb. 23rd. HAROLD DODD, Ch.M.

THE INCISION FOR APPENDICECTOMY

SIR,—In your issue for February 14th Mr. Southam condemns the gridiron incision as being relatively liable to be followed by inguinal hernia. If Mr. Southam will at each abdominal section he performs examine the internal rings for persisting processus vaginales he will find them present in sufficient instances to explain the hernias which happen to appear later. That the gridiron incision is often badly made was recognized by me years ago; in an article on this incision (*Practitioner*, April, 1912) the post-operative "hernia" is figured, but it is not an inguinal hernia.—I am, etc.,

Glasgow, Feb. 23rd. ALEX. MACLENNAN.

SERUM ANAPHYLAXIS

SIR,—In the *Journal* of February 7th there is a memorandum at page 220 dealing with the occurrence of anaphylaxis during a course of serum injections. Two cases are described. In each, anaphylaxis developed while the seventh dose of serum was being given, and emphasis is placed on the fact that only two or three days had elapsed since the date of the sixth injection. Your correspondents claim that this is in direct contradiction to the accepted teaching that serum may be given in repeated doses with complete safety, so long as an interval of less than ten days is allowed between the injections.

It is a well-known fact that serum sensitiveness rarely develops in less than ten days. In giving a series of injections one may therefore continue dosage until eight or nine days have elapsed since the first injection. If a further injection is given on the tenth day anaphylaxis, should it occur, is due to sensitization by the first dose of serum, not by the last, as your correspondents suggest. In the avoidance of anaphylaxis, therefore, it is essential that the interval between the first injection and the proposed additional dose should not be greater than nine days. If this limit has been exceeded, precautions with regard to desensitization must be taken. These observations apply equally to the intravenous and to the intramuscular routes. I have used serum extensively in the puerperal fever wards of Belvidere Hospital, and have wide experience of its action in both sepsis and septicaemia. Freedom from sensitiveness until the tenth day after the first injection is sometimes very striking, and is dependable in practically all cases.

It has frequently happened that women who have received repeated doses of serum during the acute stage of their illness, and who were serum-sensitive in a slight degree—sufficient to cause sickness, headache, fever, arthritis, and urticarial rashes—have developed these symptoms at ten-day intervals after each injection of their series. I have also seen two examples of severe anaphylaxis, in patients who had been given several injections, and who inadvertently received a further dose on the tenth day after the first of these. I have found these facts confirmed also in the serum treatment of diphtheria, although in this disease dosage after the first nine days in hospital is not often necessary. Your correspondents do not state how many days had elapsed after the primary injection in each series. I should be glad to know this. Since in each case six previous injections had been given, it seems likely that the ten-day interval had been reached or even exceeded. The information given does not, in my opinion, point to anything outstanding in either of these patients; nor does it justify a contradiction of the commonly accepted ideas on the subject of serum anaphylaxis.—I am, etc.,

MARGARET WYLIE THOMAS.

Mearnskirk Hospital, Glasgow, Feb. 21st.

GLYCERIN AS A SURGICAL DRESSING

SIR,—I am gratified at the interest that has been shown in glycerin as a surgical dressing as the result of my letter in your issue of January 10th. I am a little afraid, however, that the main point of my letter—namely, the wet-boric-lint-cum-glycerin method—is in danger of becoming obscured, and particularly so by Dr. A. Hayes Smith's communication, in which he appears to suggest that the recent correspondence has not added anything to our knowledge of the value of glycerin in the treatment of wounds, and that the statement made by Billroth in 1877 sums up the whole situation. Nevertheless I am much indebted to Dr. Hayes Smith for his reference to Billroth, because he has added to the history of the subject.

Billroth used pure glycerin in large quantities, frequently applied, and he emphasized its antiseptic and hygroscopic properties, and added a word of caution regarding its tendency to irritate and redden the region of the wound. Anyone who has used glycerin in this way knows that such a method is very messy, very irksome to both patient and attendant, and not likely to commend itself as a suitable mode of treatment. The method advocated in my letter bears little resemblance to that referred to by Billroth; neither do I maintain that glycerin acts

by virtue of its antiseptic power or its hygroscopic property. Personally I do not place too much confidence either in the antiseptic or the hygroscopic property. Probably some other factor—perhaps biochemical, as Dr. Benians's letter suggests—is responsible for the good results. I do not know; but I do know that the wet-boric-lint-cum-glycerin is both an effective and a convenient form of dressing. The actual strength of glycerin that I employ works out at about 25 to 30 per cent., and very seldom so much as 50 per cent.

On January 11th I commenced a series of experiments on the hygroscopic power of glycerin, and from what I have already learned I am tolerably certain that such large quantities of pure glycerin would require to be used to produce an effective hygroscopic flow of fluid from a wound that the process would practically be unmanageable, and I am equally certain that the weak solutions have virtually no hygroscopic power at all. Glycerin does not suck up water like a sponge. We must not forget the probability that the increased flow of serum, if there is an increased flow, may be due to the irritation caused by the pure glycerin. If I am granted space at some future date I shall be pleased to give an account of these experiments. In the meantime I should like to add that the results obtained up to the present time indicate that glycerin exerts its hygroscopic power very slowly indeed, and that water diffuses into it at such a rate that it takes at least ten days at room temperature for 2 drachms of water spread over a surface of pure glycerin with an area of 19 square inches to bring the uppermost layer of the resulting mixture to represent the strength of 85 per cent. glycerin.—I am, etc.,

Glasgow, Feb. 21st. DAVID KYLE, M.A., M.B., Ch.B.

PUERPERAL PYREXIA

SIR,—In the short communication which appears in the *British Medical Journal* of to-day's date I should have mentioned that Mellanby's most recent observations will be found in a pamphlet which was circulated at the Public Health Conference, London, November 19th, 1930. This year, at the County of Lanark Hospital, Bellshill, we have had 255 cases. As pyrexia only occurred in one case of placenta praevia and one case of hydatidiform mole, the results obtained by using antistreptococcic serum as a prophylactic agent continue to be satisfactory.—I am, etc.,

Glasgow, Feb. 28th. SAMUEL J. CAMERON.

RESEARCH ON DISSEMINATED SCLEROSIS

SIR,—The recent refusal of Miss K. Chevassut to accept the offer of the Medical Research Council of an opportunity of demonstrating a spherule in disseminated sclerosis under her own test conditions in another London laboratory has led to Sir James Purves-Stewart's dissociating himself from further collaboration with her.[1] This, together with Miss Chevassut's negative findings in a test series of cases submitted to her for examination, under arrangements made by the Medical Research Council, might create the erroneous impression that a spherule is non-existent.

We ourselves, however, working independently, although unable to confirm many of Miss Chevassut's findings, have repeatedly observed a spherule in spinal fluids from disseminated sclerosis patients. We are therefore willing to demonstrate it to any medical colleague who so desires. We are not, however, prepared to say that this is the only nervous affection in which the appearance can be seen.

Whether the spherule will ultimately prove to be a living virus, or due to some biochemical precipitation, we are not yet in a position to express an opinion. We are, however, continuing research on the subject, and hope to publish our further observations in due course.—We are, etc.,

JOHN A. BRAXTON HICKS.
F. D. M. HOCKING.

Westminster Hospital Neurological Research Laboratory, S.W., March 3rd.

LONDON CLINIC AND NURSING HOME

SIR,—I am grateful for the prompt and full answers given by the Executive Committee to the questions in my letter of February 21st. "The need for a building containing rooms suitable to *all* classes of paying patients" may be obvious, but it is surely equally obvious that if the price of the rooms provided is *8 to 14 guineas a week*—roughly the same as the charges in a score of well-known nursing homes in London at the moment—nothing is being done to assist the very class to whom serious illness presents the most acute financial problem. I still feel that this class will find the solution of their problem in graded accommodation in the large hospitals.—I am, etc.,

London, W.1, March 2nd. ERIC PEARCE GOULD.

Obituary

STANLEY ALWYN SMITH, D.S.O.

M.D., M.CH., F.R.C.S.ED.

Consulting Surgeon, Ministry of Pensions, Wales Region; formerly Orthopaedic Surgeon in Chief, Welsh Metropolitan War Hospital

We regret to record the death on February 22nd, at the early age of 47, of Mr. S. Alwyn Smith, at his country house, Pentyrch, near Cardiff. Orthopaedic surgery has been deprived of one of its most active minds, and his death has closed one of the most distinguished surgical careers in the records of the Principality. He was lecturer in orthopaedic surgery at the Welsh National Medical School, senior honorary surgeon to the Prince of Wales' Hospital, Cardiff, and also to the Shropshire Orthopaedic Hospital, consulting surgeon to the Ministry of Pensions and to the Welsh National Memorial Hospital. A sudden crippling illness had for some years debarred him from active surgical practice, but he retained to the end a keen and active interest in the work to which he was devoted.

Stanley Alwyn Smith was the son of Lieut.-Colonel T. F. Smith of Leek, Staffordshire, and spent his school-days at Repton. When he entered Edinburgh University as a medical student those who were his seniors very soon became aware that the quiet freshman who had arrived among them was a personality, modest and retiring in manner, whose presence was yet felt. Perhaps one of the secrets of his strength was his concentration on what he was doing. Whether in work or play, his self was always wholly immersed in the business in hand. A contemporary writes of him: "Looking back on those eager discussions in which undergraduates get the best part of their education, when pipes are lighted and books thrust aside, the memory remains that Alwyn Smith spoke less and was more listened to than most; it was in his personal contact with his fellow man that he made himself felt and loved." Soon after graduating M.B., Ch.B. in 1905 he became house-surgeon, and then personal assistant, to Sir Robert Jones in Liverpool, in collaboration with whom he laid the foundations of that knowledge which made him one of the world's leading authorities on disorders of the knee-joint and their surgical treatment. He proceeded M.D. in 1908, and in 1911 obtained the M.Ch. degree and the diploma of F.R.C.S.Ed.

Alwyn Smith went to Canada by invitation in 1912, and practised as a consulting orthopaedic surgeon to the Winnipeg General Hospital and the Children's Hospital. Immediately on the outbreak of the great war, he was mobilized with the Canadian Army Medical Corps, and served in France all through 1915. He was awarded the D.S.O. at Festubert in recognition of his devotion to his work, when his power of intense concentration, combined with a sturdy frame, enabled him to keep almost continuously at work during a critical time of exceptional stress. He was twice mentioned in dispatches. He returned to England in 1916 to take charge of all Canadian orthopaedic cases, and was appointed surgeon-in-chief of the Granville Special Hospital at Ramsgate. This was the first orthopaedic hospital started in England during the war, and was a model of efficiency and organization. In 1917, by special request, he was transferred to the British Army, and was placed in charge of the Welsh Metropolitan War Hospital at Whitchurch, Cardiff, as orthopaedic surgeon-in-chief. After the war Alwyn Smith became consulting surgeon to the Ministry of Pensions and surgeon-in-chief to the Prince of Wales Limbless Hospital, which later became the orthopaedic hospital for Wales. His literary output was always arresting and practical, and showed originality and sound judgement. Among his articles may be mentioned "The knee-joint" (Jones's *Orthopaedic Surgery of Injuries*), "Rupture of the crucial ligaments," "Bone grafting," "Operative treatment of knee flexion in poliomyelitis," (published in these columns in 1924), and many other very practical and helpful contributions. At the Annual Meeting of the British Medical Association at Cardiff in 1928 he was vice-president of the Section of Orthopaedics.

Alwyn Smith will be sadly missed, for not only was he a skilful and sound surgeon, but he endeared himself to all who worked with him. His patients were devoted to him, and his knowledge and help were open to all.

Sir ROBERT JONES, Bt., sends the following appreciation:

It is difficult to realize that Alwyn Smith has passed from us. Until illness seized him he was the soul of energy, full of the joy of life and work. He was a lovable character, loyal in friendship, modest, and self-sacrificing; he never harboured an unkind thought of anyone. He had the rare gift of true friendliness. In my long association with him as chief and colleague he never failed me; one could always depend upon him—his word was his bond, and his consideration and kindness whenever difficulties arose commanded one's deep affection. He did yeoman service for military orthopaedic surgery. Before any of our orthopaedic centres functioned he had started and controlled an organization of this kind in the Canadian Hospital at Ramsgate, and when, after great difficulty, I managed to have him transferred from the Canadians, his experience proved very helpful, both as teacher and as organizer. The Cardiff Orthopaedic Centre at Whitchurch, of which he had charge, was a model of surgical efficiency. He had boundless courage, both physical and moral; no difficulties appalled him; his cheery optimism and kindly tact overcame them all. There was nothing secretive in his nature; his mind was an open book; he was anxious to teach all he knew and to help all who needed help. He had all the qualities of an ideal surgeon—operative skill, a sense of proportion, sound judgement and resource, with a deep and abiding sense of responsibility, which made him a true guardian of the welfare of his patient. Orthopaedic surgery has indeed suffered a cruel blow. During his long and painful illness he displayed marvellous patience, hoping almost to the end that he would be spared to continue the great work which was his life. Our sympathy rests with his three small boys and his wonderful wife, who has tended him with a devotion and courage beyond all praise.

CYRIL OGLE, D.M., F.R.C.P.

Consulting Physician and Baillie Lecturer, St. George's Hospital

The death at Folkestone, on February 21st, of Dr. Cyril Ogle after a disabling illness of some two years' duration will sadden generations of St. George's men who, during the last forty or more years, owe him so much for teaching, example, and many kindnesses. He was born on April 19th, 1861, as the third son of John William Ogle (1824-1905), vice-president in 1886 of the Royal College of Physicians of London, and Elizabeth, daughter of Albert Smith of Ecclesall, near Sheffield, whose family subsequently took the name of Blakelock. He came of a family much connected with the hospital and school of St. George's; his father was physician from 1866 to 1876; his relative William Ogle (1827-1912) was a well-known lecturer on physiology (1869) and assistant physician (1867-1872) before he became Superintendent of Statistics at the General Register Office (1880-1893), and another William Ogle (1823-1905) of Derby was medically educated there. Cyril Ogle was unmarried, and for much of his professional life looked after his invalid father, sister, and brothers.

He was educated at Westminster (1875-80), and, like his father, at Trinity College, Oxford, where he took a second class in the Natural Science School in Trinity term 1884, and proceeded to the degrees of B.A. (1884), M.A., B.M. and B.Chir. (1890), and D.M. (1906). Entering the Medical School of St. George's Hospital in January, 1883, he qualified in 1888, and after holding resident and other appointments, especially those of medical registrar and curator of the museum, was elected assistant physician (1897), physician (1904), and consulting physician (1926). Not only was his term as physician prolonged two years beyond its ordinary limit, but his colleagues, feeling the gravity of his loss, gave him, on March, 1926, the use of four beds, and unanimously elected him Matthew Baillie Lecturer, an honour shared only by his predecessor, the late W. H. Dickinson (1832-1913). He also continued to lecture on therapeutics until 1929. At the Royal College of Physicians of London, where he became a Member in 1891 and a Fellow in 1899, he was an examiner in pharmacy (1905-9) and in medicine (1911-15), a councillor (1916-18), and censor (1924-25).

Of a very retiring disposition, though extremely tenacious of his convictions, Cyril Ogle wrote comparatively little in the medical press. But between 1894 and 1899 he contributed twenty-one papers to the *Transactions* of the Pathological Society of London; the last of these, on two pineal tumours, was specially noteworthy, as the case in a boy aged 6 years was the first recorded, at any rate in this country, of the associated sexual precocity, a feature of pineal tumours more often connected with the name of von Frankl-Hochwart, who wrote on the subject ten years later. A paper based on clinical and post-mortem investigation was that (with the late H. W. Allingham) on purulent pericarditis, with a suggestion of a method for opening the pericardial sac (*Lancet*, 1900, i, 693). He contributed the articles on pericarditis and diseases of the pericardium, and on new growths of the mediastinum to Latham and English's *System of Treatment* (1912). He was a vice-president (1922-27) of the Clinical Section of the Royal Society of Medicine.

As a physician with the clinical instinct, born of long experience, careful observation, and most conscientious hospital work, he was an outstanding example, and the accuracy of his diagnosis was remarkable, sometimes almost uncanny in its accuracy. His exceptional abilities were fully recognized by his colleagues and pupils, who paid him the well-deserved tribute of making him the doctors' doctor. A more willing and unselfish friend cannot be imagined, and it is certain that he spent his life in the service of others.

H. R.

Sir JOHN ROSE BRADFORD, Bt., President of the Royal College of Physicians of London, writes:

The profession of medicine can ill afford the loss of men of the type of Cyril Ogle, a man of solid attainments in the branch of knowledge to which he devoted himself, and one who, owing to his excessive modesty and diffidence, scarcely received the recognition to which he was entitled from his professional brethren, unless they happened by the force of circumstances to be brought into close relations with him. Physicians, in Ogle's student days, considered that the art of medicine should be based on a thorough and accurate knowledge of morbid anatomy, and Ogle himself was a remarkable example of the value of this method of training in the development of an accurate and skilled clinician. Notwithstanding his reserve and, indeed, shyness, especially with strangers, he was a most accurate clinical observer, and his diagnostic acumen was quite remarkable, so that his opinion was especially valued by his professional colleagues and by his students—and after all, that is one of the highest testimonies to the real skill and worth of a hospital physician—and judged by this standard Ogle achieved marked distinction. He did not contribute much to medical literature, and in his writings devoted himself mainly to diseases of the thoracic viscera; but his knowledge of medicine was very wide, and until his breakdown in health was well abreast of modern developments. At the College of Physicians he served on the Council, and as an examiner and as censor; in all these offices he always discharged his duties most conscientiously, and his standards were always of the highest. His friends, and especially those of long standing—and of these there were many—know what a kindly and lovable man he was, and they will mourn his loss.

ALBERT HENRY BYGOTT, M.D., D.P.H.

Medical Officer of Health, West Suffolk

Dr. A. H. Bygott, who died on February 21st at the age of 62, had been medical officer of health for West Suffolk for nearly twenty years. Until middle life he had been in general practice and in the Poor Law service in the Birmingham district. His interest in social matters was always very active, and led him, at much personal sacrifice, into the public health service. Those who enjoyed the privilege of intimate association with Bygott could not fail to be impressed with his unselfish zeal for the public welfare, to which he gave his whole attention and energy. With his wide and varied social and professional experience he yet continued to be a student, always in search of new knowledge for application to his work.

Dr. R. A. LYSTER writes:

Bygott's death means the loss of an outstanding personality not only in the public health service, but in the medical profession generally. Indifferent to praise or blame, he sought no publicity, but devoted himself entirely to the job in hand. His early struggles are known to those few who were contemporaries with him in his career as a medical student, and to them his endurance under privation, his dogged determination and perseverance, and his capacity for self-denial were subjects of amazement and deepest respect. Matriculating in 1887, he qualified first in 1893, and at once commenced practice in Birmingham. His natural genius in medicine and in surgery was quickly recognized, and he was the idol of his poor patients. In those days hospital accommodation was much more limited than now, and Bygott achieved extraordinary things in the way of urgent operations in poor homes. On the top of the work of a heavy practice he piled continuous study, and he obtained the M.B. of London University in 1900; and in 1901, when the Birmingham Board of Guardians turned their Poor Law medical staff into a whole-time service, he accepted the position of district medical officer for the Bordesley district of Birmingham. In the same year he made an unusually happy marriage. In the quieter atmosphere of the official appointment Bygott soon made short work of the fulfilment of his ambitions as regards qualifications, taking the M.D.Lond. in 1902, the D.P.H. (Birmingham) in 1903, and becoming a barrister of the Middle Temple in 1905. His real sphere was obviously preventive medicine, and he seized the opportunity to enter the public health service when the medical officer of health for Hampshire invited him to become assistant county medical officer in 1908. This was work entirely congenial to Bygott, who threw himself wholeheartedly into the big task of introducing medical inspection of schools and school children, as well as progressive public health ideals, in a county where organized medical work of any description was unknown previous to 1908. Teachers in Hampshire still remember the striking personality of the new school doctor, his tactful ways of overcoming difficulties and opposition, and his eccentricities. Subsequent promotion was rapid. He was appointed medical officer of health for Barking in 1909, and moved from there in 1912 to become county medical officer for West Suffolk.

There is no doubt that Bygott continuously overworked. He loved his work so much that he could not bear to let anyone do things for him, and he delegated grudgingly. He had found for years that his capacity for work and endurance was unlimited and that he could dispense with relaxations and hobbies and holidays, and he made the fatal mistake of thinking that he could go on indefinitely. Two years ago he had an attack of what was then diagnosed as "influenza," but which was really encephalitis, and he never recovered. He could not contemplate life without his beloved work, and so the advice of his friends who implored him to retire and to try the effect of prolonged rest and change fell on deaf ears. His work was his life, and when he found his chances of holding on to his work were fading away his life ended. A man of the highest courage—physical, mental, and moral—he could always face an issue calmly and fearlessly. Few realized what a lovable man hid behind that shy, sensitive, and abrupt manner, but to those who were privileged to share his friendship Bygott was a beloved companion whose instincts were generous and whose capacity as a loyal and devoted comrade was endless.

The announcement of the death of Mr. EDWARD LLOYD-WILLIAMS, M.R.C.S., L.D.S., on February 20th, after a short illness, will be received with deep regret by his numerous friends and former students. He received his medical education at the Middlesex Hospital and the Rotunda Hospital, Dublin, was a prizeman and Saunders scholar at the Royal Dental Hospital of London, served for many years on the staff of the Westminster and the Royal Dental Hospitals, and was a past-president of the Odontological Society of Great Britain. He had held the post of lecturer on dental mechanics, and published within a few weeks of his death a work on this subject, full of half a century's practical experience. He filled these positions, and others, with distinction, and his personality and high endeavour will be long remembered. He served as a surgeon in the Volunteers for forty years, including five years with the R.A.M.C., in France and at home, in the great war; he attained the rank of lieutenant-colonel, and was awarded the Territorial Decoration. A former colleague writes: Lloyd-Williams was a man of conspicuous ability, versatility, and enthusiasm, and his success as a teacher and a leader was due to two factors—thoroughness and self-reliance. As an instance of the former it may be stated that, when funds

were being collected in the nineties for a new hospital, he and the dean, Morton Smale, visited the chief universities and dental schools in America, in order that theirs in Leicester Square should be second to none. He was a man of fine character and deep convictions, a lay reader licensed by the Bishop of London, a Sunday school teacher, a chorister at St. Margaret's, Westminster, and, being bi-lingual, contributed papers to the Cymmrodorion Society. Never idle, he at one time or another edited the *Dental Record*, led a musical and a Shakespearean society, besides being an amateur photographer, golfer, and lawn tennis player. In his retirement at East Grinstead he devoted much of his time, both at home and on the Continent, to the welfare of the Y.M.C.A. A delightful and loyal companion, he inspired others, including the writer, a fellow-student and lifelong friend. He leaves a widow, and a son and daughter, both of whom, graduates in medicine and surgery of London University, are in general practice.

On November 20th, 1930, the death occurred in Melbourne, Victoria, of Dr. CROZIER MAGEE, late of Branxholme, aged 71. He had been ill for five months. Born in Ballarat, he first qualified in pharmacy, and travelled in New South Wales and New Zealand for Messrs. Parke, Davis and Co. He subsequently proceeded to London, attended the London Hospital Medical School, and obtained the M.R.C.S., L.R.C.P. diplomas. Returning to Australia, he practised at Penola, South Australia, and Tungamah and Branxholme, Victoria. During the small-pox epidemic in 1913 he served in the Commonwealth Government Quarantine Department at Circular Quay, Sydney. He is survived by his widow and two sons.

The sudden death of Dr. ARTHUR LAMBERT, at Harrow-on-the-Hill, came as a great shock, to both school and town. He died just as he was about to start on his round on the morning of February 12th. Sydney Herbert Arthur Lambert was born in 1867 at Georgetown, Demerara. Educated there at Queen's College, under Exley Percival, he won the Colonial Scholarship, and went to St. John's College, Cambridge. He took the Natural Sciences Tripos in 1887, studied at St. Mary's Hospital, and qualified with Conjoint diplomas and the Cambridge degrees. He became house-physician at the Brompton Hospital, and in 1894 settled down to work at Harrow. He joined the firm of Briggs and Bindloss in 1894 as assistant, and in 1896 as partner. In 1904 he took his M.D. In 1916, when Dr. Bindloss retired from the practice, Dr. Lambert became senior partner and medical adviser to the head master of Harrow. A colleague writes: Lambert's fine powers were tested severely during the influenza epidemic of 1918, when, almost alone in Harrow, save for one devoted assistant, Dr. Watney Roe (who had been invalided from the front), he had to cope with the illness of 400 boys, a large proportion of the school staff, and innumerable cases in the town. It was a dreadful time; accommodation was sadly insufficient, and nurses were not to be had; yet only one boy in the school died. For years it had been Lambert's ambition to have a new and adequate sanatorium for the growing needs of the school, and when at last, only a year ago, the new sanatorium on Sudbury Hill was opened, he said, "Now I shall die happy." The school was as much to him as he was to the school. As a practitioner he had a quick eye for the finer points of diagnosis, and was gifted with that medical instinct which only comes as the reward of knowledge and experience. His life was one of unbroken service, which he loved to give; the work had become so much part of himself that he feared the day when he should have to withdraw from practice. His patients were all his friends; to many he was their best friend. In a busy practice for thirty-six years, he never lost touch with the progress of medicine. Always believing the best of human nature, he called forth the best in everyone. Among the multitude of flowers at his funeral were to be seen tributes from every school house, fashioned in the house colours of each. Both school and town are sadly conscious of a blank which will not readily be filled; but his immediate friends are conscious, too, of an inspiration which will remain.

The following well-known foreign medical men have recently died: Dr. QUEIROLO, professor of clinical medicine at Pisa; Dr. ÉTIENNE JOURDAN, honorary professor at the Marseilles Medical Faculty; Dr. GASTON DE CAMONE, surgeon to the French Hospital at Constantinople; Dr. FÉLIX REMY, doyen of the medical profession in the Canton of Freibourg, Switzerland, aged 80; Professor CARL HIRSCH, director of the Medical Clinic at Bonn, aged 61; Dr. HERBERT HENTSCHEL, director of the infectious diseases department of the Munich University Children's Clinic, aged 30; Dr. SALOMON HENSCHEN of Stockholm, formerly professor of nervous diseases at Upsala, aged 83; Dr. RICHARD GEIGEL, a Würzburg balneologist, aged 71; Professor PROPPING, a leading Frankfort surgeon; Dr. MAX SCHILLER, a Breslau roentgenologist; and Professor WERNER KÜMMEL, director of the University Clinic of Oto-rhino-laryngology at Heidelberg, and conjoint author with von Mikulicz of a textbook on diseases of the buccal cavity, aged 64.

Universities and Colleges

UNIVERSITY OF OXFORD

The following are the days on which degrees will be conferred during Trinity term and vacation: Thursday, April 30th; Saturday, June 6th; Thursday, June 25th; Saturday, July 18th; and Saturday, August 1st. There is one degree day during the coming vacation—namely, March 28th.

UNIVERSITY OF CAMBRIDGE

DOWNING PROFESSORSHIP OF MEDICINE

The Council of the Senate has lately presented a full report on the Downing Professorship of Medicine, now vacant by the death of Dr. J. B. Bradbury. Under the charter of Downing College this chair was an integral part of the college, and the cost of Dr. Bradbury's professorship to the University Chest was small. The new statutes of the college have relieved it of any obligation to provide a fellowship, stipend, or house for future Downing professors, and if a professor of medicine were appointed the whole of his emoluments would have to be paid by the University, imposing an increased charge upon the Chest of £1,185 a year. As there is no source from which this money could conveniently be provided at present, the Council of the Senate invited a committee to consider the circumstances. This committee, comprising the Regius Professor of Physic, the Professors of Physiology, Pathology, and Biochemistry, with Dr. T. R. Elliott, Sir Walter Fletcher, Dr. H. H. Dale, Dr. T. S. Hele, and Dr. F. R. Fraser, has reported that in its opinion provision should be made in Cambridge for the furtherance of clinical medicine by research, and they would welcome the establishment of a professorship and department of experimental and clinical medicine, but this could not be done without a large benefaction. Moreover, since recent holders of the Downing professorship have been specially concerned with pharmacology—a subject which is safe in the charge of the present Reader, Dr. W. E. Dixon, of whose long services to the University and position in the scientific world the committee expresses warm appreciation—the committee does not think that discontinuance of the professorship would leave a serious gap in the medical teaching at present provided by the University, and it recommends that it be discontinued. This recommendation has been adopted by the Council, and is put forward for approval by the Senate.

UNIVERSITY OF LONDON

Mr. H. L. Eason, C.B., C.M.G., M.D., M.S., has been reappointed to represent the University on the General Medical Council.

It has been decided to institute a University (part-time) chair of medical psychology tenable at the London School of Hygiene and Tropical Medicine.

At the January Matriculation Examination there were 157 successful candidates in the first division and 649 in the second division; in addition, 43 took the supplementary certificate in Latin.

UNIVERSITY COLLEGE

The annual report of the Committee of University College, London, for the past year states that the number of students on the books of the College was 3,150: 2,513 came from the British Isles; 330 from different parts of the Empire overseas; 199 from various countries in Europe; and 108 from countries outside Europe, of whom 49 came from the United States of America. Towards the total sum of £170,000 required for the Ramsay Memorial Laboratory of Chemical Engineering £27,516 for building and equipment and £33,255 towards maintenance has already been secured through the agency of a special committee, of which the late Lord Melchett was chairman. Sir Robert Waley Cohen is vice-chairman, and Sir David Milne-Watson is honorary treasurer. Among the schemes under consideration is the provision of a new building for the department of zoology and comparative anatomy.

UNIVERSITY OF DURHAM

Sir J. Arthur Thomson, late Regius Professor of Natural History in the University of Aberdeen, has been appointed Riddell Memorial Lecturer for the ensuing year.

UNIVERSITY OF DUBLIN

At a meeting of the Senate on February 21st Sir John Rose Bradford, K.C.M.G., F.R.S., President of the Royal College of Physicians of London, was nominated to receive the honorary degree of M.D., and Professor Kappers of Amsterdam for that of Sc.D.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

COUNCIL ELECTION

The secretary of the Royal College of Surgeons has sent out the usual announcement, which on this occasion states that on Thursday, July 2nd, at 11 a.m., there will take place an election of three Fellows into the Council in the vacancies caused by the retirement in rotation of Mr. J. Herbert Fisher, Mr. G. E. Gask, C.M.G., D.S.O., and Mr. Graham Simpson.

Blank forms of the requisite notice from a candidate and of his nomination may be obtained on application to the secretary, and the same must be received by him duly filled up within ten days—that is, not later than Monday, March 16th. A voting paper will be sent by post to each Fellow whose address is registered at the College on March 31st. Fellows are requested to give notice without delay of any change of address so that voting papers may not be mis-sent.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—J. M. Durr, J. H. Ferguson, J. S. Lane, G. S. Rozario.

MEDICINE.—C. L. Ferguson, J. H. Ferguson, J. S. Lane, Walsh R. Pakenham.

FORENSIC MEDICINE.—J. H. Ferguson, E. I. B. Hawes, W. G. Kingston, S. E. Paterson, R. Schauder, C. F. Williamson.

MIDWIFERY.—R. R. Clipstein, J. H. Ferguson, D. R. Rigg, G. S. Rozario.

The diploma of the Society has been granted to Messrs. C. L. Ferguson, J. H. Ferguson, and G. S. Rozario.

The Services

DEATHS IN THE SERVICES

Lieut.-Colonel Frederick Augustus Smyth, Bengal Medical Service (ret.), died at Weymouth on January 20th, aged 89. He was born on July 27th, 1842, the son of John Smyth, Esq., of Dublin, was educated at Trinity College, Dublin, and graduated there as L.M. and L.Ch. in 1868, also taking the L.R.C.S.I. in the same year. Entering the I.M.S. as assistant surgeon on October 1st, 1869, he became brigade surgeon lieutenant-colonel on January 12th, 1895, and retired on July 27th, 1898. Most of his service was in military employment. He served in the Burmese war in 1885-86, with the Hlinedet and Yemethen columns, receiving the frontier medal with two clasps; and in the North-West Frontier of India campaigns of 1897-98, when he was P.M.O. of the Malakand Brigade, took part in the relief and defence of Malakand, was mentioned in dispatches in G.C.O. No. 1089 of 1897, and received the medal with two clasps.

Captain Spencer Stawell Crosse, M.C., R.A.M.C. (ret.), died at Kudat, British North Borneo, on February 10th. He was educated at Cambridge, where he graduated B.A., taking honours in the Natural Science Tripos, in 1909, and at Guy's, and took the M.R.C.S. and L.R.C.P.Lond. in 1912, after which he served as house-surgeon and house-physician at the Royal Berkshire Hospital at Reading. He entered the R.A.M.C. as lieutenant on February 22nd, 1917, became captain after a year's service, and retired on April 14th, 1923. He served during the war of 1914–18, and received the Military Cross on September 16th, 1918.

Captain Hugh McVicker, R.A.M.C., died of pneumonia at Peshawar on January 19th, aged 30. He was educated at Edinburgh University, where he graduated as M.B. and Ch.B. in 1925, and soon after joined the Army, attaining the rank of captain on April 1st, 1929. He was a well-known Rugby football player. While at Edinburgh he was captain of the University Rugby fifteen, and subsequently played for Richmond and for the Army, and represented Ireland five times in International matches—in 1927 and 1928. Two of his brothers had also played for Ireland.

Captain Phillip Jebb Rencontre Nunnerley, R.A.M.C. (ret.), died on November 23rd, aged 70. He was born on September 25th, 1860, entered the R.A.M.C. as surgeon on August 1st, 1885, was placed on half pay on account of ill-health on July 26th, 1898, and retired five years later, on July 26th, 1903.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The Government has withdrawn the Trade Disputes Bill which was before a Standing Committee of the House of Commons. The House this week set up a time-table for the Representation of the People Bill and went into committee on that measure. The Probation of Offenders (Scotland) Bill was read a second time.

Maternal Mortality

Miss LAWRENCE, replying to Mr. Freeman on March 3rd, gave a list of the numbers of women in England and Wales who had died in childbirth attributed to pregnancy and child-bearing in the years 1919 to 1929. The list showed that in 1919 the total number of maternal deaths was 3,028; in 1920, 4,144; 1921, 3,322; 1922, 2,971; 1923, 2,892; 1924, 2,847; 1925, 2,900; 1926, 2,860; 1927, 2,690; 1928, 2,920; and 1929, 2,787. The figures for 1930 were not yet available. No reliable estimate could be formed of the proportion of maternal deaths in those years which were preventable, but in its recent report the Departmental Committee on Maternal Mortality estimated that of the deaths brought under its notice, which it had no reason to suppose were other than fairly representative of the total, no fewer than one-half were preventable. No information showed the number who received no pre-natal supervision, or the proportion of deaths among these women compared with those who received such assistance. The Departmental Committee, however, had recorded its opinion that, while the number of women who received ante-natal supervision was increasing, there was still a large section of the population which did not realize the advantages of such supervision.

Cerebro-spinal Fever

On March 3rd Mr. Freeman asked the Secretary for War whether, in view of the fact that of the 13 cases of cerebro-spinal meningitis at Aldershot, of which 8 had already proved fatal, 12 sufferers had been recently vaccinated, he would consider the desirability of suspending compulsory vaccination in the Army. Mr. SHAW replied that Mr. Freeman was under a misapprehension. Only two of the patients had been vaccinated within six months. The remaining ten were vaccinated at dates varying from six months to more than four years before they fell ill of cerebro-spinal fever. That only one of the patients was unvaccinated could be accounted for by the rule that no recruit was accepted unless he had been vaccinated or was willing to be. He was advised that there were no grounds in the present outbreak for suspending the rule.

Paratyphoid Fever

Questioned by Colonel Howard-Bury on February 26th, Mr. GREENWOOD stated that inquiries made by a medical officer of his Department in conjunction with the local medical officers of health appeared to have shown that the origin of the outbreak of paratyphoid fever in Essex was one of the employees at a dairy farm, who, unknown to himself, was suffering from the disease; 256 cases, including secondary cases, had occurred up to the present, and there had been seven deaths. The preventive measures taken included the removal to hospital of the man considered to have been the source of infection, the cleansing and disinfection of the premises, milk utensils, etc., and the employment of a fresh staff of workers at the farm.

Replying to Mr. White on February 26th, Mr. GREENWOOD said he was advised that the paratyphoid organism was easily destroyed by heat, and that any of the methods of treatment by heat in general use, if carried out with proper care, were effective in destroying this organism. Milk was not allowed to be sold as "pasteurized" unless it had been treated by the method prescribed by his Department, and as this method was now being used to an increasing extent he did not think it necessary to take any special steps to encourage its adoption.

Milk Purification

Mr. GREENWOOD told Mr. Hurd, on February 26th, he was not at present satisfied that the abolition of the licence fees for graded milk would have the effect of encouraging the supply of pure milk, but he would consider the matter in consultation with the Chancellor of the Exchequer and the Minister of Agriculture, and also with representatives of local authorities, when opportunity occurred for the general revision of the Special Designations Order.

Replying to Dr. Fremantle on February 26th, Mr. GREENWOOD said that the memorandum on human and bovine tuberculosis was now in proof, and he hoped to publish it shortly.

Vaccination

Replying to Mr. Carter on February 26th, Mr. GREENWOOD said that he had the whole subject of vaccination under consideration, but could not in present circumstances undertake to introduce legislation suspending the compulsory clauses of the Vaccination Acts, as suggested. The compulsory requirements of the Vaccination Acts were in effect limited to infants under 12 months of age, and in this class the occurrence of post-vaccinal encephalitis had been practically negligible. In Holland a compulsory measure had been suspended, but it related to the vaccination of children at school age. He added that since January 1st, 1930, a total of seven cases of post-vaccinal encephalitis had been reported, two of which had proved fatal.

Questioned by Mr. Groves on February 26th, Mr. GREENWOOD said that public vaccinators and vaccination officers were statutory officers, and their office could not be abolished without fresh legislation. The appointment of these officers had recently been transferred to the local health authorities, and he did not propose to consider the question of introducing any such legislation until those authorities had more experience of their new duties. Under present conditions the appointments in question might be held jointly with other offices, such as that of district medical officer and registrar of births and deaths.

Influenza

Replying to Mr. Freeman on February 26th, Mr. GREENWOOD stated the number of deaths in England and Wales from influenza during the years 1918 to 1930 to be respectively: 112,329, 44,801, 10,665, 8,995, 21,498, 8,461, 18,986, 12,721, 8,936, 22,263, 7,754, 29,084, and 5,002. Influenza had been more prevalent in January and February than during the corresponding period of 1930, but considerably less than during that period of 1929. The numbers of deaths varied substantially from year to year, and it was not possible to ascribe this variation to any particular cause.

Doctors' Cars

Replying to Mr. Hore-Belisha on February 25th, Mr. MORRISON said there was no distinction in appearance between a doctor's car and an ordinary private car. He would deprecate any attempt to establish a priority of right of way for doctors' cars by the use of a distinctive type of motor horn or other similar means. Such a course would be open to serious abuse.

Change of Doctor.—On March 2nd Mr. Gossling asked the Minister of Health if the recent change in the Medical Benefit Regulations by which insured persons must give longer notice of their wish to transfer from one insurance doctor to another was made with the approval of the British Medical Association. Miss LAWRENCE replied that the appropriate steps were taken to bring this proposal to the notice of the British Medical Association as soon as the Minister of Health had formed the opinion that any further protection of insurance funds which could be secured by this means ought to be secured without avoidable delay. The whole subject was fully discussed at the Annual Conference of Local Medical and Panel Committees in October, and a resolution was passed requesting the Minister to defer the consideration of the matter for a year. The Minister was sensible of the importance which attached to the principle of free choice of insurance doctors by insured persons, but complete freedom of choice was not accorded by the Regulation which had now been amended. The matter was therefore one of degree, and he decided that it was his duty to take action without the interposition of any prolonged period of delay such as had been suggested to him on behalf of the Association.

Royal Veterinary College.—Dr. ADDISON told Sir George Courthope, on February 25th, that the Treasury had sanctioned from the Development Fund, towards the cost of reconstructing the Royal Veterinary College, grants amounting to £150,000, provided the Governors obtained from other sources a sum of £100,000. Other conditions attached to the grants, but the Governors had accepted them. The Governors had now raised a sum slightly above £50,000.

International Conventions.—On March 2nd Dr. Fremantle asked the Foreign Secretary why the two Conventions relative to the treatment of prisoners of war and for the amelioration of the condition of the wounded and sick of armies in the field, signed by the representatives of Great Britain, the Dominions, and India on July 27th, 1929, had not been presented to Parliament for ratification. Mr. DALTON said that a number of legal questions had had to be examined in connexion with these Conventions, one of which would require legislation to bring it into effect.

[The text of these Conventions has now been issued as White Papers.]

India: Medical Research.—Mr. BENN told Major Pole, on February 25th, that he had sent him, in March, 1930, a copy of a debate in the Indian Legislative Assembly which showed that the Government of India had decided to summon a conference to inquire into the most suitable centre for the proposed central medical research institute and other matters. This conference was held in July, and passed a resolution (the official members not voting) that a central medical research institute on the lines advocated by the Fletcher Committee should be located at a university centre as soon as financial conditions permitted. The Government of India was considering this resolution, but anticipated that it would not be possible to bring the institute into existence either at Dehra Dun or elsewhere as long as the present financial stringency continued.

Indian Medical Service.—On March 2nd Mr. BENN told Major Pole that, so far as could be foreseen at present, it was not proposed to make any alteration in the method of recruitment to the Indian Medical Service pending the enactment of constitutional reforms.

Notes in Brief

It is estimated that between 60,000 and 100,000 persons will have their period of insurance extended for another year as a result of the passing of the National Health Insurance (Prolongation of Insurance) Act, 1930.

Medical News

As already announced, Professor Edward Mellanby, M.D., F.R.S., will give the fourth Sir Charles Hastings Lecture in the Great Hall of the British Medical Association's House in London on Friday, March 13th, at 8 p.m. The subject of his lecture is "Diet and Health." The chair will be taken by Lord Moynihan, President of the Royal College of Surgeons of England, and after the lecture relevant questions in writing will be invited. Admission is free, by tickets obtainable on application to the Financial Secretary, B.M.A. House, Tavistock Square, W.C.1. Seats not occupied by ticket holders by 7.50 p.m. will be available for other members of the public.

At a meeting of the Illuminating Engineering Society, to be held in the Lecture Theatre of the Institution of Electrical Engineers, at Savoy Place, Victoria Embankment, W.C., on Thursday, March 19th, there will be a discussion on modern domestic lighting.

At a meeting of the Royal Sanitary Institute, to be held on Friday, March 20th, at 5 p.m., in the Technical College, Lincoln, discussions will be held on houseboats on inland waterways, and refuse collection and disposal.

Particulars of the lectures and demonstrations arranged for next week by the Fellowship of Medicine will be found in our Diary of Post-Graduate Courses, published in the *Supplement* at page 76. Copies of syllabuses and tickets of admission can be obtained from the Fellowship, 1, Wimpole Street, W.1.

A series of lectures, with demonstrations, on the care of the child, for nurses and health visitors and others interested in the welfare movement, will be delivered at the Infants Hospital, Vincent Square, S.W.1, on Wednesdays at 6.30 p.m., commencing on April 15th, when Dr. Eric Pritchard will discuss breast-feeding. The series will conclude on June 3rd with a lecture by Miss M. G. Thomson on the management of the child in the nursery school. The fee for the course is 5s., or 1s. for a single lecture.

Lectures and practical courses of instruction for the diploma in psychological medicine were resumed at the Maudsley Hospital on March 4th. The course includes twelve lectures on morbid psychology, eight on treatment and on the psychoneuroses, four on mental abnormalities of children and on the legal relationships of insanity, six on crime and insanity, and three lecture-demonstrations on laboratory methods. There will be six clinical demonstrations in psychiatry, twelve in neurology, two on abnormalities of the fundus oculi, and four on the pathology of the nervous system. Particulars may be had from the director of the Central Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E.5.

The forty-sixth Congress of the Berlin Society of Balneology will be held in Bad Ems, from April 7th to 11th. One of the main subjects for discussion is the treatment of asthma by hydrological methods. Visits will be paid to several mineral water resorts, and the use of this form of treatment in various morbid conditions will be discussed. Further information may be obtained from Dr. Max Hirsch, Steglitzerstrasse 66, Berlin, W.35.

The first Congress of the International Stomatological Association will be held at Budapest from April 14th to 19th, under the patronage of the Hungarian Government. Further information can be obtained from the secretary of the congress, 14, Varosha-ulca, Budapest IV.

On the proposal of the Spanish Government the Council of the League of Nations has decided to hold a conference on rural hygiene at Geneva on April 3rd, to which representatives of all the European nations will be invited.

The first scientific meeting of the recently founded German Society for Internal Medicine and Neurology in the Czechoslovakian Republic is being held at Prague on March 7th and 8th, when the chief subject for discussion is the modern treatment of blood diseases.

The annual meeting of the International Society against the State Supervision and Regulation of Prostitution will be held at Strasbourg and Colmar from April 30th to May 2nd.

A special number of the *Bruxelles-Médical* has been issued, containing accounts of the various scientific and social functions which were held in the course of the congress known as the Journées Médicales from June 28th to July 2nd, 1930, in connexion with the commemoration of the centenary of the declaration of Belgian independence. Abstracts of the more prominent papers read are included. A summer cruise is being arranged this year by the *Bruxelles-Médical* on the new steamship *Foucauld*. Starting from Zeebrugge on July 12th, the party will visit the Norwegian fjords, the Lofoden Islands, the North Cape, Lapland, Spitzbergen, the icefields, and the Faroe Islands; the tour ends on August 8th. The charges for medical practitioners, their wives, and unmarried children under the age of 21 is from £16 second class, and £36 10s. first class. Further details may be obtained from the Section des Voyages de Bruxelles-Médical, 29, Boulevard Adolphe Max, Brussels.

The *Popular Science Monthly* has awarded G. R. Minot of Boston and G. H. Whipple of Rochester (U.S.A.) a prize of 10,000 dollars for their introduction of the liver treatment of pernicious anaemia.

Dr. Leslie Charles Broughton-Head has been appointed Honorary Surgeon Dentist to His Majesty the King in Scotland in succession to Mr. J. H. Gibbs resigned.

Madame Nageotte-Wilbouchewitz has been elected president of the Société de Pédiatrie de Paris.

The Secretary of State for the Colonies has approved a change of title from Deputy Director, Health Service, to Assistant Director, Health Service, Sierra Leone.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

A Case of Dyspnoea

"G. D. G." (Leeds) asks for suggestions for the treatment of the following case of dyspnoea: The patient, a woman aged 66, has had attacks of acute dyspnoea every night for several years. The attack lasts from two to three hours, and always comes on after she has been asleep some little time. There is some slight wheezing, and expiration is prolonged. During the attack the blood pressure rises, and on one occasion it was 234/75 mm. Hg; between attacks it had varied from 148/78 to 210/85. The appearance of the patient suggests a renal origin; the urine from time to time contains a very slight amount

of albumin, the specific gravity being usually 1010. The heart is somewhat enlarged, and the first sound at the apex is duplicated. Treatment already tried has included nitroglycerin, mannitol nitrate, asthmatic mixtures of all kinds, and thyroid gland tablets. Lately she has had liquor morphinae at night and a mixture of tincture of digitalis and potassium bromide during the day. This had some success for a time. Some temporary relief is obtained by taking a half-grain tablet of ephedrine hydrochloride during the attack.

Paroxysmal Rhinorrhoea?

"Ninety-nine" writes: I have a female patient, aged 7½ years, who has paroxysms of sneezing in the mornings, lasting two or three hours. The paroxysms occur at all times of the year and at quite irregular intervals, and are accompanied by profuse watery discharge, making the child very exhausted. Between attacks she seems perfectly well and suffers from no other condition referable to the nose or to any anaphylactic type of disease. There seems to be no local abnormality (other than slightly enlarged tonsils), and all methods of treatment, local and general, have failed. Suggestions for treatment will be welcomed.

Treatment of Sciatica

Dr. E. M. MACDERMOTT (Galway) writes in reply to the correspondent who inquired about the use of quinine-urea-hydrochloride injections in sciatica (February 21st, p. 336): I have only personal experience of three cases—one of many months' standing, which, as well as my second case, was completely relieved by injecting 10 c.cm. of a 10 per cent. solution. The patient with long-standing sciatica remained perfectly comfortable for months, but has recently had a slight return of his trouble. The third patient was not permanently relieved, but this is not a case of pure sciatica, being secondary to a hydrops tubae profluens of nine years' standing; even she got complete relief for four days, followed by a period of comparative comfort for a long time.

Majorca

Dr. F. GILBERT SCOTT (Cala Mayor, Palma-de-Mallorca, Spain) writes in reply to "C. M.'s" queries (February 21st, p. 335): The water in the towns of Majorca is satisfactory, so, too, is sanitation; in the smaller places less so. There is no sudden change of temperature at sundown such as is met with on the Mediterranean coast. For rheumatism the dry climate is distinctly good. The rainfall is less than 15 inches per annum.

Sir HARRY BRITTAIN (London, S.W.) has sent us a reprint of an article in praise of Majorca which he contributed recently to the *Windsor Magazine*. We gather that copies of this leaflet are obtainable from the Spanish Travel Bureau, Ltd., 87, Regent Street, W.1.

Income Tax

Commencement of Partnership

"R. S. G." entered into partnership ("an entirely new business") on April 1st, 1930. After that date he and his partner received cheques in payment for work done before the partnership came into existence. How should those receipts be dealt with? Further, he purchased a new motor cycle in April, 1930, for £25, and part exchanged it in November, 1930, receiving £15 towards the cost (£41) of a new cycle. What can he claim for cost of renewal and depreciation?

*** The receipts in question need not be brought into the partnership account for income tax purposes, especially as, being a new partnership, the practice will presumably be assessed on the basis of the value of the year's "bookings." The out-of-pocket cost of renewal can be claimed up to the extent to which it is a renewal and not an improvement; this amount will be £25–£15=£10. Depreciation cannot be claimed for the same year as that for which the computation is affected by the "renewal" claim. When "R. S. G." replaces the new cycle by another, or a car, he can make a further claim. If he does not replace it in 1931 he can claim a depreciation allowance on the £41 cycle for 1932–33.

Charge for "Rent" of Surgeries

"Z. Y. X." has two surgeries. A is a house for which he pays £140 per annum inclusive. The top is let off at £110 inclusive, and the lower portion is occupied by a rent-free caretaker in return for his services as surgery receptionist. B is owned by "Z. Y. X." and would probably let at an inclusive rent of, say, 27s. 6d. per week; in fact two rooms are retained for use as surgery and the rest of the premises are let for £1 per week. What allowances should "Z. L. X." claim?

*** In each case the method of calculation is to decide what proportion of the total rental value of the premises represents the professional use and to claim that ratio of the total cost. For instance, if in the case of A the upper portion represents one-half of the rental value, then the amount to be claimed in computing the professional profits is one-half of £140=£70. It is assumed that no services are rendered to the tenants who pay a rent, in which case the profit on subletting—that is, £110–£70=£40—represents income which is chargeable under Schedule A only and cannot be brought into the Schedule D assessment.

LETTERS, NOTES, ETC.

"Bad Risk" Operation Cases

Dr. B. E. COOK (Anaesthetist, Doncaster Royal Infirmary) writes: Years ago, in Manchester, I heard Professor D. P. D. Wilkie lecture before the Medical Society, and his latest paper on acute appendicular disease is as admirably concise, original, and stimulating as that remembered address. Recently Professor Donald of Manchester read a paper on progress in surgery (*British Medical Journal* p. 354), in which he refers to a possibility of future advances, since "anaesthetists were opening up new fields by their research for methods of reducing shock." It is in these desperate emergency cases to which Professor Wilkie refers that all these methods—such as the use of CO_2 and O_2, liberally, during and after operation—should be employed, and have already proved their value in saving numbers of "bad risk" cases, in which the prognosis before operation was extremely bad.

The Gordon Memorial College, Khartum

The wing in the Gordon College, Khartum, which has for many years been occupied by the Wellcome Tropical Research Laboratories, is now required for school extension, and it is proposed to remove them to a specially erected building. In the annual report of the college for 1929 attention is called to the remarkable reduction in the death rate which followed the installation of these laboratories. The extensive irrigation scheme which has been constructed latterly to promote the cultivation of cotton in the Sudan has brought into existence a very large number of possible breeding places for mosquitos, thereby involving the laboratories in still further work. At an interim meeting of the committee and trustees of the college, held in London last July, Major Archibald, director of the laboratories, reported that 25,000 cases of malaria and splenomegaly had been treated; the splenic rate had been reduced from 70 to 35 per cent. in the previous six months, special attention having been paid to children. The incidence of bilharziasis had been similarly diminished, and in these ways much had been done to assist the progress of the Gezira cotton scheme. The number of boys in the college has risen from 86 in 1918 to 554 in 1930. During the year nine boys passed out of the college into the Kitchener School of Medicine.

Sterilization of Mental Defectives

Dr. B. DUNLOP (London, S.W.7) writes: The Eugenics Society announces in its quarterly review that it has drafted a Bill, which may soon be introduced in the House of Commons, to legalize voluntary sterilization of the mentally deficient. I beg you will allow me to suggest that before the view be thus accepted that voluntary sterilization is illegal, a Ministerial pronouncement on the question should be obtained.

The Certified Patient's Pension

Correction

We much regret an error in the paragraph published on February 21st (p. 325), under the heading "The Certified Patient's Old Age Pension." In the seventh line the word "an" should read "no."

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 51, 52, 53, 54, 55, 56, 57, and 60 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 58 and 59.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 75.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

219 Acute Benign Infectious Myelitis

As a rule myelitis caused by such organisms and toxins as those of the typhoid and influenza groups, if not fatal, usually results in prolonged illness and chronic invalidism. The sensory and motor disturbances in these patients invariably remain. There is, however, a recoverable type of myelitis, as has been reported by Strauss and Rabiner, and I. J. SANDS (*Journ. Amer. Med. Assoc.*, January 3rd, 1931, p. 23) records four such cases. Following infection of the upper respiratory tracts, there occurs in young patients paralysis of the lower extremities, with loss of the deep tendon and abdominal reflexes, retention of urine, and subjective and objective sensory disorders which show a segmental distribution. Slight leucocytosis is present, and the spinal fluid has an increased protein content and shows relatively slight evidence of any cellular reaction. Recovery is apparently rapid and complete. The present cases were evidently due to an unknown infectious agent producing an invasion chiefly of the cord and, to a lesser extent, of the roots, causing radiculitis and paraplegia with bladder disturbance. Recovery was complete in all but one instance, in which residual pyramidal tract involvement persisted. Even in this patient the only complaint was constipation. No specific treatment was tried. While such cases may be due to a new organism, Sands suggests that they may represent an attenuated form of epidemic encephalitis. Strauss has recommended the use of foreign protein intravenously, and Sands adds that he has employed this in other forms of subacute inflammatory cord and brain diseases with considerable benefit.

220 Epidemics of Acute Myalgia in Iceland

R. K. RASMUSSEN (*Ugeskrift for Laeger*, January 15th, 1931, p. 56) traces the development of the seven epidemics of acute myalgia which have been observed since 1856 in Iceland. The second occurred in 1865, the third in 1900, the fourth in 1911, the fifth in 1915–1917, the sixth in 1926-1927, and the seventh and last in 1928. These outbreaks were characterized by stabbing pains in the muscles of the chest and abdomen and, in some cases, by dry pleurisy and catarrhal phenomena. The incubation period was always less than ten days, and adults, principally males, were most often attacked. The overwhelming majority of the cases occurred in the summer and autumn. In the first, second, fourth, and fifth epidemics the disease was limited to one particular district. It was this district which suffered most in the sixth outbreak, which began in Reykjavik in June, 1926, and spread rapidly over large parts of the island; 565 cases were notified in that year. Though the leading clinical characteristics were sufficiently uniform in all seven epidemics to justify the conclusion that their etiology was identical, the incidence of fever and pleurisy varied very much in the different epidemics. Thus it was only during the fourth epidemic that the patients were invariably febrile; in the others (apart from the first two, in which observations on the temperature were lacking) cases of high fever alternated with subfebrile cases and with those in which the temperature was not raised at all. In the fifth epidemic all the patients suffered from pleurisy, the outbreak earning for itself the term " pleuritis epidemica." In the other epidemics pleurisy occurred only now and then, and it was conspicuous by its absence in certain areas in the epidemic of 1926. It would therefore seem that pleurisy was no more than a complication which occurred with variable frequency in different outbreaks of one and the same disease, and was not to be regarded as a cardinal and pathognomonic symptom. The author considers that a better term for this disease is " rheumatoid infection."

221 Pernicious Anaemia

J. F. WILKINSON and W. BROCKBANK (*Acta Med. Scand.*, December 16th, 1930, p. 211), after discussing the vague gastro-intestinal, cardiac, and nervous symptoms which often precede the recognition of the typical pernicious anaemia, characterized by raised colour index, anisocytosis, and relative lymphocytosis, have selected seven out of a series of 150 cases to illustrate the difficulties often met with in making an early diagnosis of this disease. They suggest that, besides a complete blood examination, a fractional test meal should be a routine procedure in all cases of weakness and anaemia, persistent diarrhoea, and soreness of the tongue, all cases of paraesthesia, and all undiagnosed cases of gastro-intestinal disease, particularly those of doubtful carcinoma of the stomach.

222 Tetany Complicating Enteric Fever

C. GARDÈRE and J. SAVOYE (*Journ. de Méd. de Lyon*, January 5th, 1931, p. 21) state that tetany may occur during the progress of any of the exanthemata, but it appears to be a rather rare complication of enteric fever, occurring usually in moderately severe cases, and with equal frequency among children and adults. The complication exhibits the classic symptoms of carpo-pedal spasm, associated with flexure of the distal portions of the limbs upon the proximal segments. The prognosis is favourable, and the tetany runs a clinical course corresponding to that of the enteric fever, spontaneous recovery being the general rule. The etiology is obscure. Among several hypotheses it has been suggested that *B. typhosus* has a specific toxic action on the parathyroid glands, but this has not been demonstrated. It may be that enteric fever excites tetany in patients who have a latent spasmophilia. The authors refer to many cases recorded since 1855. They describe the case of a delicate boy, aged 3 years, who recovered from a moderately severe attack of enteric fever. Although the intermittent spasms were severe, there was no trismus, nor symptoms of meningitis. Parathyroid extract was given daily, and calcium chloride later; as no improvement resulted from twelve days' administration, the authors resorted to ultra-violet irradiation. The blood calcium content was practically normal. They add that there is on record a case of tetany supervening two years after an attack of enteric fever. No familial history of spasmophilia has been noted in any of the recorded cases.

Surgery

223 Volvulus of the Stomach

G. BARBERA (*Il Policlinico*, Sez. Chir., January 15th, 1931, p. 1), who records a fatal case in a woman aged 48, illustrates the rarity of volvulus of the stomach by the fact that Boppe could find only 44 cases in the literature up to the end of 1928, the first case having been reported by Mazzotti of Bologna in 1874. According to Heberer and Kocher, the stomach may undergo torsion on its two axes. The first of these passes from the cardia to the pylorus, constituting the axis of the stomach; torsion on this axis is known as " organo-axial." The second axis passes perpendicularly to the first through the lesser omentum, uniting the two curvatures at the central point, and being continued below the greater curvature on the gastro-colic ligament. Volvulus on this axis is called " mesenterico-axial." Of the 44 cases collected by Boppe, 23 were of the organo-axial and 18 of the mesenterico-axial type; in three the nature of the volvulus was not sufficiently described for identification. Ulcer of the lesser curvature is a frequent cause, having been found in 15 cases owing to adhesions or perigastritis to which it gives rise. In the majority of cases, as in Barbera's patient,

the cause is ptosis, gastric dilatation, or laxity of the ligaments. The principal symptoms are violent attacks of pain, tympanitic swelling of the epigastrium, absence of vomiting (contrasting with intestinal obstruction), and inability to pass a sound into the stomach. The mortality is always very high. Treatment consists in simple untwisting of the torsion (7 recoveries and 3 deaths), or untwisting the torsion followed by an operation such as resection or gastro-enterostomy (14 cases).

224 Prevention of Peritonitis in Colon Surgery

According to F. W. RANKIN and J. A. BARGEN (*Arch. Surg.*, January, 1931, p. 98), prophylactic value attaches to the injection of a vaccine prepared from streptococci and colon bacilli with a view to preventing peritonitis from following surgical operations on the colon. This conclusion is based upon a series of 222 vaccinated cases, which is contrasted with another of 58 cases during the same period operated upon for similar conditions, no vaccine being given. Eleven deaths from peritonitis occurred among the 222 cases, while there were thirteen deaths among the 58 non-vaccinated patients. The vaccine is prepared from streptococci and colon bacilli recovered from the peritoneal exudate in a case of peritonitis. It is suspended in sodium chloride solution and introduced by a blunted spinal puncture needle into the peritoneal cavity. Other preventive measures include the thorough cleansing of the large intestine and relieving any obstruction by supplying a residue-free diet, and administering laxatives and colon irrigations. The authors mention that in one week the same surgeon operated upon two patients of similar build, age, surgical risk, and identical lesions; the unvaccinated one died within a week from general peritonitis, while the vaccinated one made a smooth, uneventful recovery. The pre-operative measures, with the exception of the vaccine, were the same in both. Animal experiments have shown that protection can be established against otherwise fatal peritonitis. Since the immunity obtained by the vaccine injection is relatively transient, the operation should take place within twenty-four hours after the administration of the vaccine; the peritoneal injection and hyperaemia in these cases was found to be marked, and indicated increase of the blood supply of the part, and its flushing with an increased number of phagocytes.

225 Causes of Thrombosis

W. KÖNIG (*Zentralbl. f. Chir.*, January 17th, 1931, p. 130) comments on the great increase of post-operative thrombosis and embolism in recent years. The three necessary factors are circulatory changes, damage to the vessel walls, and alterations in the blood itself. A fresh extract of crushed muscle injected into an animal will produce all these changes, as will also the toxin which Freund found in defibrinated blood. After injection of either of these substances there is a fall of blood pressure; congestion in the lungs, liver, extremities, and right ventricle; and a diminution in the number of platelets in the blood. The platelets also break down more readily than usual, and are more easily agglutinated. Chemical changes in the blood, such as increased protein breakdown and a rise in the non-protein nitrogen figure, also occur. These changes also take place after operation, the vascular engorgement of the extremities being shown by the temperature of the sole of the foot, which is raised for several days. There is a special tendency to thrombosis if the low platelet count fails to rise in a few days' time. Several substances may be responsible for these effects and thus predispose towards thrombosis, but adenosin—a product of nuclear destruction—is probably the most important. Statistics show that thrombosis is commonest in cases of tumours, fractures, and inflammatory conditions where nuclear breakdown is especially likely to occur. The bearing of these considerations on the prophylaxis and treatment of thrombosis has not yet given rise to practical results, but there is evidence that the injection of the patient's own blood prevents the fall of the platelet count after operation.

Therapeutics

226 Hyperpyrexial Treatment of Dementia Paralytica

C. A. NEYMANN and S. L. OSBORNE (*Journ. Amer. Med. Assoc.*, January 3rd, 1931, p. 7) describe the results obtained by treating with diathermy 25 patients suffering from dementia paralytica. Large electrodes were applied over the chest and back of the patient, and currents of between 4,000 and 6,500 milliamperes were passed; precautions were taken to avoid the occurrence of burns, the most dangerous sites being near the iliac crests. Clinical remissions occurred in 16 cases, and lasted for not less than four months. All the patients showed reduction of blood pressure, and the authors consider that this and the changes in the blood chemistry which were observed were due to the profuse perspiration which ensued. No harm of any kind was caused, and this the authors attribute to the fact that great care was taken to prevent the temperature from rising too rapidly or above 105°, the optimum degree being stated as 103.5°.

227 Local Treatment of Varicose Ulcers

C. FOUQUET (*Bull. Soc. Franç. de Derm. et de Syph.*, December 9th, 1930, p. 1306) claims to have improved all cases treated by Bourggraff's method since commencing outpatient treatment at Nanterre in June, 1930, and to have cured many patients in periods varying from a few weeks to a few months, according to the extent of their lesions. The method consists in cleaning the ulcer with ether, and then applying a layer, one centimetre thick, of a paste of bioxyol, which has a basis of zinc peroxide; in contact with alkaline serous discharges this liberates ozonized oxygen. Around the ulcer, and covering the area of dermatitis which usually surrounds it, is spread a layer of a substance with an ichthyol base; the whole region is then covered with sterile gauze, and bandaged with a tarlatan (not cotton) bandage. The patient is recommended to put on an elastic bandage, with the leg elevated, before getting up in the morning, and to keep this on all day. In contrast with methods depending mainly on correction of the venous stasis, the dressing requires changing every two or three days. It is claimed that the ozonized oxygen has both a healing and an anaesthetic action, and that the pain of an ulcer frequently disappears after the first application.

228 Pyloric Obstruction Relieved by Medical Treatment

W. DE SCRIVER (*Canadian Med. Assoc. Journ.*, January, 1931, p. 99) describes the case of a man, aged 73, who presented clinical and radiographical evidence of well-marked pyloric stenosis, but who responded nevertheless to medical measures, an operation having been refused. When first seen he had abdominal pain with marked emaciation and debility, a moderate degree of arteriosclerosis, and pronounced dehydration. The abdomen was full in the upper half, but flattened below; no peristalsis could be detected, but there was a palpable and easily heard succussion splash. The *x*-ray diagnosis was pyloric stenosis caused probably by a duodenal ulcer, and giving rise to at least twenty-four-hour gastric retention. Atropine administration having proved useless, the stomach was washed out twice daily, and intravenous injections of glucose (400 c.cm. of a 20 per cent. solution) and normal saline solution were given. Feedings of orange juice, egg-nog, and milk were added on the third day; however, when the tube was passed in the morning there was always a large residue from the previous day. After five days the patient's condition was much better, but an operation was still refused; the feedings were therefore increased, and the patient was trained to pass the stomach tube. The gastric residue gradually decreased in amount, and the patient eventually returned to his work. A later *x*-ray examination showed the stomach empty after six hours. The three points on which Scriver bases his success in this case are the intravenous therapy which arrested the dehydration, the frequent lavages, and the small fluid feeds.

Laryngology and Otology

229 **Chronic Otitis Media**

G. F. SHAMBAUGH (*Arch. of Otolaryngol.*, December, 1930, p. 753) believes that only in exceptional cases of chronic suppurative otitis media is there any serious menace of complications arising, and only for such cases are operative measures advisable. It may be necessary to eradicate a focus of bone-invading disease, such as a caries or cholesteatoma in the attic, the aditus, or the antrum, but such a procedure is not to be classed as unsuccessful if, as is often the case, the otorrhoea persists subsequently. Shambaugh distinguishes between two forms of chronic otitis media. In the first the disease involves the mucosa lining the cavities of the middle ear, and serious complications do not ensue. In the second the underlying bone is also affected, and there may be dangerous sequels. In differentiating between the two types the history is important; thus most cases referable primarily to scarlet fever or measles are not complicated by caries or steatoma, the infection involving only the mucosa, and the discharge being stringy and mucoid. In bone-invading disease there is often a persistent offensive odour, a granular residue in the discharge, and the presence of the white flakes characteristic of cholesteatoma. The author supports his cautious attitude towards extensive operations by arguments based an anatomical conditions. He outlines the possibilities of conservative local treatment, recommending irrigation, the instillation of hydrogen peroxide and boric acid in alcohol, and the insufflation of powdered boric acid.

230 **Examination of the Upper Respiratory Tract**

H. K. PANCOAST (*Journ. Amer. Med. Assoc.*, November, 1st, 1930, p. 1318) emphasizes the value of *x*-ray examination in cases of laryngeal disease, and describes his own technique. Careful screen examination precedes the taking of films, and the condition of the laryngeal ventricles, both at rest and on phonation of the vowel sound A, is carefully noted. In a normal larynx the cigar-shaped air-containing ventricle is well seen, and the arytenoids, being surrounded by air, are also easily seen; their position and mobility must be observed. The pharynx, pyriform sinuses, and trachea are examined in this order. The patient is then given thin barium cream, and the swallowing act observed. The author distinguishes four stages of deglutition as seen on the *x*-ray screen: (1) the mouth is full of the opaque mixture, and the tongue moves backwards; (2) the mixture enters the pharynx, the epiglottis moves backwards, and the larynx rises until the arytenoids touch the epiglottis; (3) the oropharynx is obliterated and the larynx still further elevated, differentiation of the arytenoids and epiglottis being no longer possible; and (4) the pharynx and pyriform sinuses empty, and all structures return to their normal position. In tumours of the larynx there is direct evidence of a localized nodule encroaching on the air spaces, and obliteration of the ventricles, which occurs also in inflammatory conditions and in paralysis of the cord; in the latter the cigar-shaped ventricle is obliterated entirely, or in the lower half or in the lower posterior portion only. Inflammatory conditions are manifested by swollen arytenoids, retrolaryngeal swelling, obliteration of the ventricles, and narrowing of the tracheal opening. The presence and extent of post-inflammatory stenosis is always well indicated; the ventricles are obliterated and the vestibule is narrowed. The upper portion of the trachea becomes funnel-shaped, or is entirely shut off some distance below the larynx. The author describes the *x*-ray appearances seen during speech in two patients who had been subjected to total laryngectomy. In the first case the pharynx and upper oesophagus filled with air, the cricopharyngeus muscle appeared as a distinct band, and the air reservoir slowly emptied while the patient counted from one to eight. In the second case the reservoir did not fill so well, but a continuous supply was maintained, and the patient was able to talk for a long period by taking in air through the nose.

231 **Tonsillectomy**

I. SYK (*Nordisk Medicinsk Tidskrift*, November 8th, 1930, p. 711) of Stockholm has performed approximately 2,500 tonsillectomies during the past eight years without a single death in the course of the operation or the subsequent convalescence. He attributes this achievement to his technique, the details of which were described in 1924 in *Acta Oto-Laryngologica*, vol. vi. He prefers the complete operation, irrespective of anatomical and pathological conditions, extensive adhesions, and other complications. The normal structures of the palate are retained, and the operation is always performed under light general anaesthesia, whatever the age of the patient. The operation itself taking only 25 to 40 seconds, the general anaesthesia is so light that, though consciousness is lost momentarily, the reflexes associated with swallowing and coughing are retained. With regard to pulmonary abscesses as a sequel to tonsillectomy under general anaesthesia, the author suggests that their comparative frequency in the Anglo-Saxon countries is entirely due to the completeness of the general anaesthesia induced. He thinks that the rarity of the operative and post-operative haemorrhages occurring in his cases is due to a detail in the technique. Under the general anaesthesia it is possible to pull the tonsils out of their bed in such a way that the tortuous blood vessels are stretched; accordingly, when they are divided, they retract within the muscular bed, in which they soon cease to bleed. On no occasion did he find it necessary to ligature blood vessels in a child. In view of this successful series Syk concludes that with the technique advocated no objection can be raised to the removal of the tonsils by a specialist. Tonsillotomy, on the other hand, is, in his opinion, a gamble so far as its technical execution is concerned. The operator may not succeed in removing what he wishes to remove, and the results are not infrequently complicated and impaired by cicatricial adhesions and other undesirable sequels.

Obstetrics and Gynaecology

232 **Full-term Ectopic Pregnancy**

A. S. WILSON (*Journ. Med. Assoc. of South Africa*, December 27th, 1930, p. 761) reports a case of an ectopic pregnancy in a 6-para which went to full term. After the patient, an Indian woman, had been in labour for two days medical aid was obtained. Although the labia were tremendously swollen, the head was well up and partially fixed. Owing to the patient's condition internal version was performed. With some difficulty the legs were pulled down; there was slight trouble with one arm, and then the after-coming head became fixed; forceps were applied, and it was delivered. Resuscitation failed, but it was concluded that had there been no delay in delivering the head, the child, which was normal in every respect, would have survived. While trying to express the placenta it was noticed that the cord did not descend. The patient was then removed to hospital, but manual delivery of the placenta was impeded by a cord-like structure, which on removal was found to be the intact uterus. On the fifth day a large recto-vaginal fistula developed, and five days later in another hospital a small piece of the anterior lip of cervix was found to be still attached to the vaginal wall; behind this the examining finger passed into a thick-walled cavity closely resembling the uterus. When the abdomen was opened two bands of yellow omentum were found shutting off the vagina below and forming a mass about the size of a normal uterus; the rest of the abdomen was clear. There were no adhesions and no free fluid. Loops of bowel were free and uninjected, and there was no boggy vascular mass indicating where a placenta might have been attached. Two later operative attempts reduced the fistula to a pin-point in the left posterior fornix. Wilson concludes that the case was one of a full-time ectopic pregnancy, and that the foetus had been violently driven through the pouch of Douglas, ripping the uterus almost completely from its attachments.

233 Nephritis in Pregnancy

E. J. STIEGLITZ (*Amer. Journ. of Obstet. and Gynecol.*, January, 1931, p. 26) records statistics of 55 cases of nephritis in pregnancy, and defines three main classes: the nephritis of pregnancy—a syndrome of renal fatigue; eclamptic intoxication; and pre-existing renal and/or vascular disease which has been exacerbated by the pregnancy. In a fourth group he places cases having other complications such as cardiac disease, thyrotoxicosis, infections, and obstetric difficulties. In the first of these classes, comprising about 40 per cent. of cases of nephritis in pregnancy, the most notable characteristics are the abrupt onset of symptoms at eight months; slight raising of the arterial tension; albuminuria and moderate oedema; the late average date of delivery; and the excellence of the late results. These cases contrast sharply with the abrupt onset of acute symptoms in the eclamptic class. In the author's opinion the evidence incriminating the placenta is stronger than that which points to other factors, such as foetal elements. He believes that administration of alkalis to the point of alkalinization of the urine in nephritic patients is inadvisable and risky. Diuresis is best induced by giving water and acid salts, if necessary, such as calcium chloride, calcium nitrate, or ammonium chloride. The reduction of excessive arterial tension is accomplished by administering orally bismuth subnitrate in daily doses of 10 grains. Prognosis may be based on the degree of anaemia and of renal functional impairment; the age of the patient; and the promptness with which improvement follows delivery.

234 Intrauterine Lipiodol Injections in Sterility

G. COTTE (*Lyon Méd.*, January 4th, 1931, p. 3) concludes from his own experience and from cases reported in the literature that the employment of lipiodol injections of the uterus and tubes for the diagnosis of sterility of tubal origin in certain cases cures the sterility itself. He prefers this method to insufflation with air or carbon dioxide, since with it more cures are obtained. Two reasons are given to explain this action of lipiodol: as in insufflation, tubes with impaired permeability are cleared of all obstruction; and secondly, owing to its high iodine content, the drug has a local action on the tubal epithelium. Cotte believes that the accidents which have been reported are due much less to the method than to its ill-timed use. Nevertheless, as with all intrauterine instrumentation, these injections are not without some risk, and should only be given in those clinically negative cases in which they can furnish necessary diagnostic information. Before their administration a minute clinical examination should be made to determine the absence of gynaecological lesions, such as lesions of the adnexa or recent salpingitis, which would contraindicate their use. To avoid all inflammatory reactions, the injections should preferably be given during the week following the menstrual period. It is advisable that in all cases when radiography shows that the lipiodol has overflowed from the os the patients should be kept in bed for twenty-four hours.

235 Pregnancy Complicated by Tabes

The occurrence of repeated pregnancies in a tabetic patient is reported by J. T. WILLIAMS (*New England Journ. Med.*, January 15th, 1931, p. 119), who states that in such circumstances the gastric crises may be interpreted erroneously as pernicious vomiting, or as the onset of premature labour. Typically, however, the pains are often unperceived by the patient, affects and thus painless; the second stage, however, is often painful, owing to the failure of the abdominal muscles, especially the uterine contractions. The most important in cases of pregnancy is the temporary increase in the ataxia, due to the change in the patient's centre of gravity. The degeneration in the column of Goll in tabes results in uterine anaesthesia, and also in rapid dilatation of the cervix. Discussing the nervous supply of the uterus, Williams suggests that the cerebrum may exert an inhibitory action, one indication of this being the augmentation of uterine contractions, which can be observed during Caesarean section under spinal anaesthesia.

Pathology

236 The Influence of Intense Effort upon the Leucocyte Count

H. GOUNELLE and J. WARTER (*Arch. des Mal. du Cœur*, December, 1930, p. 757) have investigated the effect of intense muscular exertion upon the total and differential leucocyte counts in trained and untrained men. The subjects of the first group were young soldiers, while the second consisted of medical students; the test exercise was running a distance of one or two kilometres, examinations of the blood being made before, immediately after, and half an hour after the test. It was found that this exercise was followed at once by an increase of 30 to 40 per cent. in the total leucocytes in the trained individuals, whereas in the untrained an increase of 70 to 100 per cent. was produced. The "leucocytosis of movement" was only transient, and in all the subjects had disappeared within half an hour after the test. A reduction in the percentage of polymorphonuclear neutrophils was observed to follow intense effort, but the *actual numbers of these cells were, if anything,* increased. A large percentage of and actual increase in the numbers of circulating lymphocytes and monocytes accompanied the relative reduction in neutrophil polymorphs. The differential white count returned to normal within half an hour of the test exercise. The authors refer to earlier work in which contraction of the spleen and increase in red cells of the blood were found to accompany muscular exertion. They believe that this action of the spleen underlies the change they have demonstrated in the leucocyte count, but that other factors also play a part. The practical importance of their work lies in the technique of the leucocyte count; a patient in whom this examination is to be made should remain at rest for about half an hour before the blood is drawn.

237 The Action of Liver Extract on Blood Regeneration

M. P. CRANE, ISABEL HOWARD, and W. P. MURPHY (*Amer. Journ. Med. Sci.*, December, 1930, p. 803) have investigated the effect of administering daily a potent liver extract, equivalent to 800 grams of liver, for a period of 14 days to four normal young men; there were no striking changes in the blood. There was a small rise in the number of the red cells, but it was never more than 700,000 per c.cm. above the average control figure. There was a similar tendency to raise the haemoglobin figure during the latter days of the test, and a slight rise in the reticulocytes reaching 3, 1.3, 1.4, and 1.1 per cent. respectively. The authors point out that, although this percentage is small on a basis of 5 million red cells per c.mm. in circulation, it would correspond with actual reticulocyte figures of between 150,000 and 55,000 per c.mm., and with a 15 per cent. reticulocyte rise in a patient with 1 million red cells, as met with in severe pernicious anaemia. The rise was transitory, persisting only for one to three days.

238 Structure of Rheumatic Nodules

M. H. DAWSON and R. H. BOOTS (*Journ. Amer. Med. Assoc.*, December 20th, 1930, p. 1894) comment on the close histological similarity between the subcutaneous nodules which occur in rheumatic fever and rheumatoid arthritis. Each nodule consists of a central area of necrosis, due apparently to gelatinous swelling and disintegration of collagen bundles; round this is a zone of large mononuclear cells disposed radially, and, further outwards, a sheath of dense and avascular fibrous tissue. The arterioles and capillaries in the surrounding tissues show a subendothelial deposit of fibrin, with hyperplasia of the subendothelial cells, narrowing or occlusion of the lumen, and in some instances canalization of the hyperplastic intima. Their elastic coats are split, and there may be polypoid protrusions into the vessel lumen. Around the vessels there may be detected an infiltration by large mononuclear and small round cells. Bacteriological investigations were entirely negative. No relationship was demonstrated between these nodules and those of syphilis, gout, or tuberculosis.

THE FOETUS AND VITAMIN D

THE GOULSTONIAN LECTURER for 1930, considering the significance to clinical medicine of studies in calcium and phosphorus metabolism, said of pregnancy: "a high calcium diet of adequate vitamin content is required by pregnant and lactating women to allow for the drain of calcium into the foetus, and especially through the mother's milk."

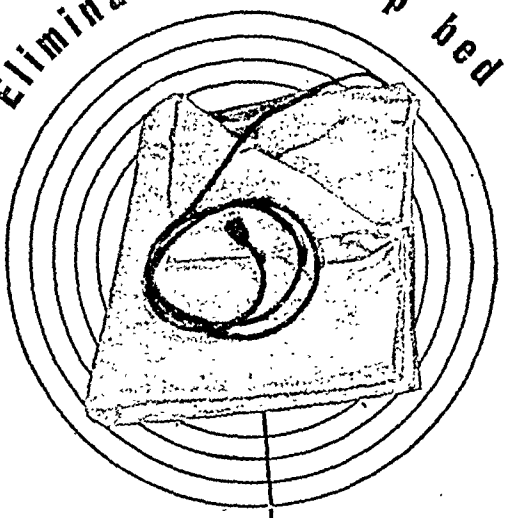
Ostelin vitamin D is physiologically standardised, and is available in combination with calcium in the following forms especially suited to the mother's requirements during pregnancy:

1. OSTELIN TABLETS. Ostelin m. iii with calcium glycerophosphate gr. ii.
2. OSTELIN EMULSION. The same in the form of emulsion.
3. GLAX-OVO. Supplies milk, with its natural lime salts; vitamin D in the form of Ostelin; the whole pleasantly flavoured with chocolate.

Ostelin vitamin D is also incorporated in Sunshine Glaxo, a fully humanised milk food for infants.

Free trials of any of these preparations may be had on application to Glaxo Laboratories, 56, Osnaburgh Street, London, N.W.1

Eliminate the damp bed



Electrically aired and warmed

With THERMEGA ELECTRIC BLANKETS and PADS, constant regulated heat can be supplied to beds immediately from any wall plug or lamp socket on any voltage (100—250).

A THERMEGA BLANKET will warm and air a bed all through well within the hour. Thus all risk of rheumatism is avoided. By means of the THERMEGA PAD, steady warmth can be applied locally at a moment's notice, and maintained for as long as is desired. The pad is no larger than an ordinary hot-water bottle.

Their average cost of current works out at ½d. an hour (at 6d. a unit). By a special Thermostat device the heat is constantly regulated and overheating made impossible. Prices from 33/- complete.

Ask for demonstration and particulars from medical stores, electrical firms, leading stores, or direct from the manufacturers,

RELIEVES CONSTIPATION

Test Sal Hepatica for yourself and you will agree that it is by far the most satisfactory laxative yet developed. There is no pleasanter or more effective way of eliminating from the system harmful toxic amino acids. The presence of such evils in the system gives rise to rheumatism, lumbago, neuritis and many other maladies that have their source in auto-intoxication. Remember too that Sal Hepatica is essentially non-habit-forming. It's daily administration leads to a "time habit" which is invaluable in combating chronic constipation.

Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in an effervescent medium.

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession on application to Bristol-Myers Company, 112, Cheapside, London, E.C 2.

THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted, a banking account offers. Perhaps it is assumed that to conduct an account by post involves 'more letter writing', or is costly, or is not welcomed by the Bank. It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method, and offers some clear suggestions.

The Secretary of the Bank will be pleased to send a copy on application

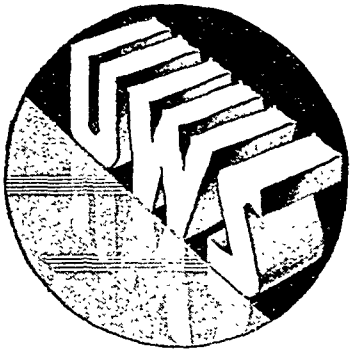
THE MOST SATISFACTORY METHOD OF ENSURING A SOFT WATER SUPPLY



Special Booklet Sent Free on Request
"Soft Water in the Home," an illustrated sixty-four page booklet, will gladly be sent to any doctor upon request.

It is a fact of considerable significance that 'Permutit' Water Softening Plants are to-day to be found in over 15,000 homes, and in the leading hospitals, clubs and hotels. No chemicals are used in the 'Permutit' System. This plant provides a soft water which is healthful and palatable to drink, at a moderate initial outlay and an infinitesimal running cost. The plant can be fitted without any alteration to existing arrangements.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

COURT HALL, KENTON, EXETER,

SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: Teignmouth 289.

HAYDOCK LODGE,

NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-contained villas and gardens, in which patients are encouraged to occupy themselves in farming, gardening, indoor and out-door recreation. For terms, prospectus, etc., apply

TYKEFORD ABBEY, NEWPORT PAGNELL,

BUCKS.

FUNCTIONAL NERVOUS DISORDERS, MEDICAL & CONVALESCENT CASES.

An approved Nursing Home for reception of Female Cases under the Mental Treatment Act.

The Home is a Mansion of Historical interest, standing in 9 acres of garden and grounds, and is situated 14 miles from Northampton, and 12 miles from Bedford on the main London to Northampton Road, [illegible] miles from London. Both sexes are accommodated. Psycho-therapeutic treatment is used freely in suitable cases. Radiant Heat, X-Ray, and Ultra-violet Light. Billiards, tennis, golf. Fees from five guineas per week.

Apply, Dr. D. E. M. DOUGLAS MORRIS. *Telephone*: Newport Pagnell 121.

The MAUDSLEY HOSPITAL

DENMARK HILL, S.E.5.

Telephone: RODNEY 4841—2.

A CLINIC instituted by the London County Council for Treatment of NERVOUS and CURABLE MENTAL DISORDER. Voluntary patients ONLY RECEIVED.

OUT-PATIENTS—2 p.m.: MEN—Mondays and Thursdays. WOMEN—Tuesdays and Fridays.

IN-PATIENTS: (*a*) 189 beds (both sexes) in wards or separate rooms. (*b*) 13 private rooms (for ladies) with special sitting rooms, garden, and dietary.

TERMS:

(*a*) **£5 a week, but in case of patients with a legal settlement in the County of London a less sum may be charged according to means.**

(*b*) **£6 6s. a week.**

Terms include (with rare exceptions) all forms of treatment, for which exceptional facilities exist—there being a staff of consultant specialists and the central laboratory of London County Mental Hospitals being attached to the hospital. Inquiries of EDWARD MAPOTHER, M.D., F.R.C.P., F.R.C.S., Medical Superintendent.

BARNWOOD HOUSE,

GLOUCESTER.

A REGISTERED HOSPITAL for the CARE and TREATMENT of LADIES and GENTLEMEN suffering from NERVOUS and MENTAL DISORDERS. Within two miles of the G.W. Railway and L. M. & S. Railway Stations at Gloucester, the Hospital is easily accessible by rail from London and all parts of the United Kingdom. It is beautifully situated at the foot of the Cotswold Hills, and stands in its own grounds of over 280 acres. Voluntary boarders of both sexes are also received for treatment.

Special accommodation for Lady Voluntary Boarders is also provided at the MANOR HOUSE, which has its own private grounds and is entirely separate from the main Hospital.

For particulars as to terms, etc., apply to—ARTHUR TOWNSEND, M.D., Medical Supt.
Telephone: No. 7 Barnwood.

County Borough of West Ham.

EDUCATION COMMITTEE.

APPOINTMENT OF CHIEF ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from fully qualified and registered Medical Practitioners for appointment as Chief Assistant School Medical Officer.

The person appointed will be required to work under the supervision of the School Medical Officer, and to devote the whole of his or her time to the service of the Education Committee.

Salary £750 per annum, rising by biennial increments of £50 to a maximum of £900 per annum.

APPOINTMENT OF ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are also invited from fully qualified and registered Medical Practitioners, with special experience in Refraction, for appointment as an Assistant School Medical Officer under the direction of the School Medical Officer. The person appointed will be required to devote his or her whole time (mainly in connection with defective vision) to the service of the Education Committee. Salary £500 per annum, rising by annual increments of £25 to a maximum of £700 per annum, allowance being made in respect of similar service under other Local Authorities in fixing the commencing salary in accordance with the scale agreed between the British Medical Association and the Local Education Authorities.

Applicants must have had not less than three years' experience since qualification, and should have had previous experience in the medical inspection and treatment of school children. A diploma in Public Health will be an advantage.

General conditions applicable to the above appointments—

Application will be made for the recognition of the above appointments as designated posts under the Local Government and Other Officers Superannuation Act, 1922, and subject to such recognition the successful applicants will be required to pass a medical examination as required by the Council for the purposes of that Act, and the statutory contributions of five per cent. to the Superannuation Fund will be deducted from their salary. In the event of the appointment of a woman, such appointment will be automatically terminated on marriage.

Canvassing members of the Education Committee or the Council, either directly or indirectly, will be considered a disqualification

Forms of application, together with particulars of duties, may be obtained from the School Medical Officer, Town Hall, West Ham, E.15, upon receipt of a stamped addressed envelope, and should be returned to the undersigned not later than Monday, March 23rd.

CHARLES E. CRANFIELD,

County Borough of Croydon.

SENIOR DENTAL SURGEON.

Applications are invited from Male Licentiates in Dental Surgery for the post of Whole-time Senior Dental Surgeon. Salary £600, rising by £25 per annum to £700 p.a.

The person appointed will be in charge of the Dental arrangements under the supervision and control of the School Medical Officer. The duties will consist chiefly in the inspection, re-inspection, and treatment of children attending the elementary schools of the Borough, but will also include dental work under the Council's and Child Welfare and Tuberculosis Schemes. The person appointed will also be expected to give instruction in dental hygiene as and where required. There are two whole-time Assistant Dental Surgeons.

Previous experience in the dental treatment of children is essential.

Applications, on a form to be obtained from the undersigned, accompanied by copies of not more than three testimonials, must be received by me not later than 11 a.m. on Monday, March 16th, endorsed "Senior Dental Surgeon."

Town Hall, Croydon. JOHN M. NEWNHAM, Town Clerk.
February 25th, 1931.

The Rural District Council of CHESTERFIELD.

MEDICAL OFFICER OF HEALTH.

Applications are invited from registered Medical Practitioners for the above appointment.

Candidates must possess a Diploma in Public Health and must have had administrative experience in Public Health.

The area of the district is 68,158 acres and the estimated population 85,000, but one of the terms of the appointment requires the gentleman appointed to accept the appointment of Medical Officer of Health in the Clay Cross Urban, Dronfield Urban, and Norton Rural Districts, on a vacancy arising in those Districts.

The salary will be £900 per annum, plus a travelling allowance of £70 per annum.

The appointment, which is a designated post under the Local Government and Other Officers Superannuation Act, 1922, will be made subject to the approval of the Minister of Health.

The gentleman appointed will be required to perform all the duties of a Medical Officer of Health as defined by Orders made from time to time by the Minister of Health, to devote his whole time to the duties of his office, not to engage in private practice, and to reside at a place approved of by the Council.

Applications, stating age, qualifications, and experience, together with copies of not more than four recent testimonials, which will not be returned, should reach the undersigned not later than March 17th.

Public Assistance Offices, Newbold Rd., Chesterfield. F. W. BROOM, Clerk to the Council.

Valentine's Meat-Juice

In the **Gastric Form of Influenza** and its **Debility,** in **Typhoid** and **Acute Pneumonia,** in the **Exhaustion** of **Phthisis** and **Pulmonary Diseases, Valentine's Meat-Juice Sustains** and **Strengthens**

When Other Food Fails

THE quickness and power with which VALENTINE'S MEAT-JUICE acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.

Physicians are invited to send for brochures containing clinical reports.

For sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,

Richmond, Virginia, U. S. A.

SAVED BABY'S LIFE!

PORTE'S CAESAREAN OPERATION

In 'The Scottish Nurse' for January 1931 appeared an article by a Scottish State Registered Nurse describing an exceedingly severe operation—*Porte's Caesarean Section* which she underwent in Malta at the hands of a well-known surgeon.

Twenty-four hours after the second stage of labour had begun it was discovered that delivery was impossible. The womb had become septic and the Porte Caesarean was performed, the baby being safely extracted.

The condition of the mother was then highly critical, and the baby had to be revived by artificial respiration. For a week after birth she weighed only five pounds. The mother, despite intense pain and weakness, endeavoured to nurse her, but as progress appeared stationary she was put on alternate feeds of Cow & Gate Full Cream Milk Food and Breast.

From then onwards she made rapid progress and at four months the mother weaned her altogether.

Now eight months old, the child is the picture of contentment and happiness and weighs over 17 pounds.

"Smiler" fed on Cow & Gate

COW & GATE MILK FOOD

has saved more baby lives than any other preparation in the world

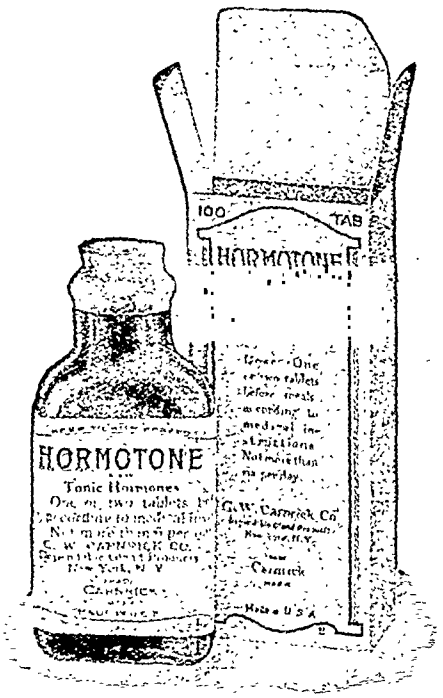
ASTHENIA and the Fatigue Syndrome

are usually conditions in which a definite pathology cannot be demonstrated.



Hormotone
BRAND

has proved its value in treatment, through its action in:

Stimulating cell metabolism,
Increasing the respiratory exchange,

and

Raising to normal the low blood pressure usually attendant upon such conditions.

Dose: One or two tablets three times daily before meals.

Pernicious Anæmia

TRADE MARK 'WELLCOME' BRAND
LIVER EXTRACT

(An Active Selected Fraction of an Extract of Fresh Liver)

Prepared by a process tested and found efficient by the Medical Research Council. Clinical evidence has established the value of 'WELLCOME' LIVER EXTRACT in pernicious anæmia.

Liver treatment is also indicated in cases of secondary anæmia due to hæmorrhage, such as hæmatemesis or post-partum hæmorrhage; suggested in conditions due to liver dysfunction, in the vomiting of pregnancy and pre-eclamptic conditions and in the anæmia of sprue.

(See Wellcome's Medical Diary, 1931, pages 111-113)

Reduced facsimile

In tubes, each containing an active selected fraction of an extract derived from half-a-pound of fresh liver.

DIRECTION.—
The contents of one tube, or more, daily, in soup or water.

Price in London to the Medical Profession
32/5 *per box of* 12 *tubes*

A MASTERPIECE OF ARCHITECTURE, IN WHICH ARE ILLUSTRATED TWO FEATURES CREATED BY THE ISLAMIC CIVILISATION.—Byzantium, Egypt, Persia, India and Latin Spain contributed elements out of which, with additions of their own, the architects of Islam constructed a beautiful, original and characteristic style, recognisable, wherever seen, by the minaret and the bulbous dome. The earlier mosques had no minaret, the idea having apparently been first suggested about A.D. 700 by the great lighthouse at Alexandria, the top of which the Moslems converted into a prayer chamber. The name applied to the tower of lighthouse form, which henceforth became an essential feature of the mosque in all countries, was the Arabic MANARAT—a lighthouse. From it was made the call to prayer.

THE "RECENT ADVANCES" SERIES

"Methods of treatment change so quickly that such publications as the 'Recent Advances' Series are invaluable to the general practitioner, too busy, as he usually is, for post-graduate study."
—BRITISH MEDICAL JOURNAL.

"The 'Recent Advances' Series published by Messrs. J. & A. Churchill meets a want in medical literature by providing a concise, yet sufficiently detailed summary of developments in the theory as well as in the practice of the various specialities into which medicine is gradually resolving itself."
—EDINBURGH MEDICAL JOURNAL.

HEALTH AT THE GATEWAY

By E. W. HOPE,

Professor of Public Health in the University of Liverpool.

With 25 Plates, Maps, and Plans. Demy 8vo. 15s. net.

A history of the administrative developments affecting the Public Health of the city and port of Liverpool. Few workers for the public good in great cities have the inclination or the opportunity to record for the benefit of their colleagues the results of their own experience in administration and the history of past efforts. In this book Professor Hope has told the story of the growth of a great city and the gradual assumption by competent authority of power to control the public services.

THE PRINCIPLES OF EPIDEMIOLOGY

AND THE PROCESS OF INFECTION

By C. O. STALLYBRASS, M.D., D.P.H.,

Chief Assistant Medical Officer, City and Port of Liverpool.

Fully illustrated. 30s. net.

Clinical medicine, pathology, bacteriology, and immunology all bring grist to the epidemiologist's mill. Latterly, mathematical and experimental methods have been applied to his problems, and the author has endeavoured to present in this volume a systematic summary of the knowledge so obtained. His book is intended primarily for the Medical Officer of Health who has little leisure to read the ever-increasing volume of specialized writings on the subject.

THE CONCENTRIC METHOD

IN THE DIAGNOSIS OF PSYCHONEUROTICS

By M. LAIGNEL-LAVASTINE,

Professor in the Faculty of Medicine of Paris.

10s. 6d. net.

The author enjoys an international reputation for his work on the Sympathetic Nervous System, which he here relates to general diagnosis in a series of ten clinical lectures. One feature of the book of particular interest is that it shows the attitude adopted by the author and his school to what he calls "certain psychometaphysical wanderings born of the work of Freud."

THE MONGOL IN OUR MIDST

By F. G. CROOKSHANK, M.D., F.R.C.P.

31 plates and diagrams. 21s. net.

An entirely re-written and greatly enlarged version of a book which appeared, some years ago, in the TO-DAY and TO-MORROW series. In the present volume, enlarged to over 500 pages, Dr. Crookshank takes up with considerable spirit the challenges laid down by those who queried the validity of the opinions set forth in the earlier book. The broader issues involved are treated in a spirit of independence and humanity.

Since Aneroid Gauges depend for their action on the stretching, under pressure, of metal diaphragms, they are subject to the usual errors arising from the elastic properties of metals.

The Lifetime Baumanometer, on the other hand, operates on the immutable law of gravitation—and does not depend for its action on the material used in construction.

Portability, the only excuse in the past for using aneroid instruments, of doubtful accuracy, is now equally obtainable in the Lifetime Baumanometer.

Moreover, all Lifetime Baumanometers are individually calibrated, scientifically accurate, and guaranteed to remain so. Everyone is a MASTER instrument and carries our exclusive guarantee against glass breakage.

The Lifetime Baumanometer's distinguishing specifications, have won for it the approval of more than one hundred thousand doctors the world over.

Among the many models to choose from, is the New Kompak Model—the smallest, lightest, handiest, mercurial instrument.

Your surgical instrument dealer will gladly demonstrate it or send one to you.

The I·XL STAINLESS STEEL PHYSICIAN'S POCKET KNIFE

A pleasure to own and delightful to use.

Polished Buffalo Horn Handle

4/-

Each

No. 7222.—*This is a knife we have made for nearly 100 years. Its description appears in one of our old pattern books dated 1858, and was probably copied from an older one.*

ORIGINALLY designed for the Physician, this knife, by virtue of its long, useful, highly polished blade, now made of Stainless Steel, is to-day being used most extensively as a Fruit Knife—in fact, no better knife could be found for this purpose. It is also most useful for opening letters, cutting the leaves of a book, sharpening pencils, and many more purposes which a good knife can serve. The Nickel Silver cap on the end can be used on sealing-wax, or for pressing down tobacco in the pipe. The Physician will still find the long blade of this knife extremely useful for its original purpose—that of taking powder from broad-necked bottles.

There is an I·XL stockist in every district, but as this is a knife designed mainly for Physicians, and there is not a large sale, we are not asking our dealers to stock it.

If you wish for one of the knives, send us Postal Order for 4/-, and we will send it to you through our local dealer.

Before buying Cutlery, fill in the Coupon, place a halfpenny stamp on the envelope and post to-day. →

OUR GUARANTEE

We are sure you will like the knife, but if for any reason you are not entirely satisfied, please return the knife to us within 7 days, and we will promptly refund your money in full.

To GEORGE WOSTENHOLM & SON Ltd., 105, WELLINGTON STREET, SHEFFIELD.

Please send me free of charge your new 28-page Catalogue of the celebrated I·XL Cutlery, illustrating and describing a wide range of Pocket Knives, Table Knives, Razors, Scissors, Carvers, and the wonderful I·XL Saw-Edged Bread, Salad and Grape Fruit Knives, with the name of the Dealer in my district who sells I·XL Cutlery.

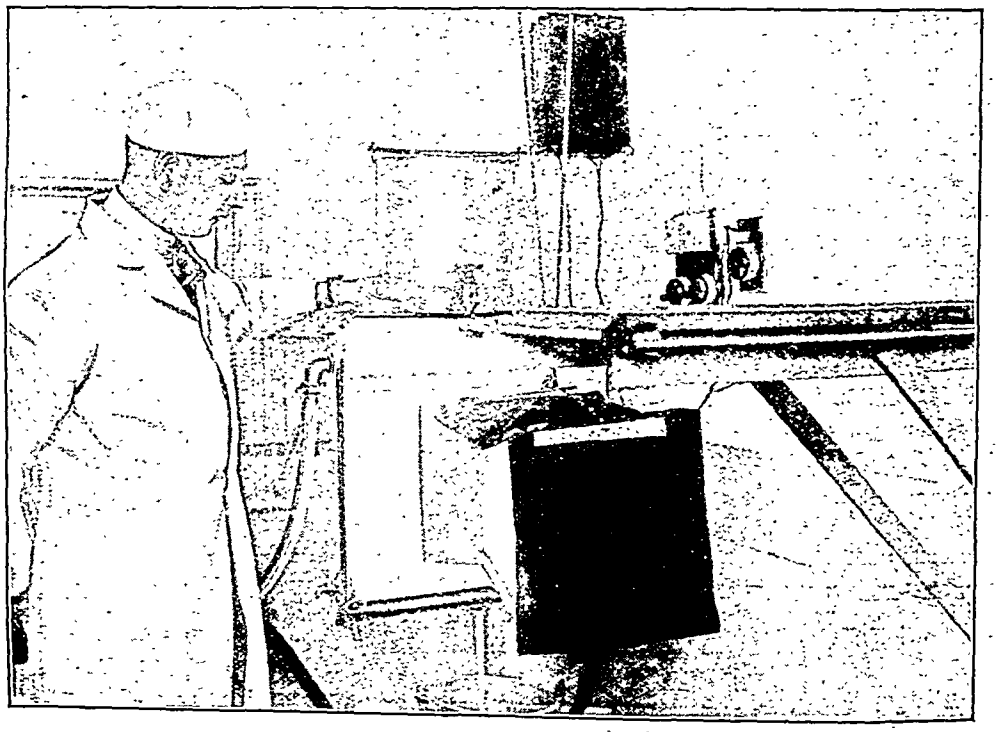
MICKLEFIELD IRRADIATED MILK



TREATING THE MILK

By this Process—

(1) VITAMIN A AND NATURAL FLAVOUR ARE PRESERVED.
(2) VITAMIN D CONTENT IS INCREASED 1,800 PER CENT., OR TEN TIMES THAT OF ANY OTHER IRRADIATED MILK.

One pint equivalent in Vitamin D to 600 drops or 12 grammes of average Cod-Liver Oil.

A ten weeks' test recently conducted at the Infants' School, Rickmansworth, under the supervision of the Medical Officer of Health, gave the following results:—

(1) 18 children (controls) had their usual ordinary milk.
(2) 29 " 1/3-pint of Grade A (T.T.) milk five days a week.
(3) 30 " " Micklefield " " "

(1) Average increase in height .605-in. (2) Average increase in weight 9.72 ozs. more than (1).
(2) " " " .610-in. (3) " " " 10.9 ozs. more than (1).
(3) " " " .744-in.

Full particulars appeared in an article in the LANCET, January 18, 1930, p. 127, et seq., a reprint of which will be sent post free on request.

The milk is delivered every week-day in London; elsewhere by arrangement.

Write to J. O. HICKMAN, MICKLEFIELD GREEN, RICKMANSWORTH.

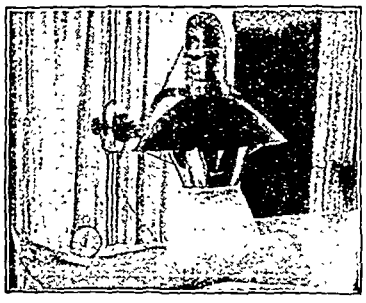
LUMINOUS HEAT RAYS

Relief of pain in conditions of acute inflammation . . .

A new booklet!



The Sollux lamp in use.

"In pleurisy and inflammation of the lungs, irradiation with the large Sollux Lamp quickly relieves pain. *If for this reason only, no doctor should be without the Sollux Lamp.*"
—One leading authority's opinion.

This booklet summarises for you actual clinical experiences in the treatment of many acute and chronic conditions, including:—Abscesses, boils, bruises, extravasations, sprains, synovitis, torticollis, lumbago, rheumatism, neuritis, sciatica, mastoiditis, otitis, sinusitis, rhinitis, prostatitis, epididymitis, orchitis, acute dental conditions, etc.

Send in your request TO-DAY

HYPERAEMIA therapy with luminous heat rays gives prompt relief of pain and speedy resolution in many conditions. Acute inflammatory pain, chronic neuritic and rheumatic disorders—these are outstanding indications.

The new booklet published by the Hanovia Company on this subject gives much valuable information and evidence in many cases of this kind. In special conditions, too, this booklet summarises results from a large number of cases of interest, collected together in a simple, compact form.

This is a little work you should not be without. A copy will be sent to you free upon request to the address on the coupon below.

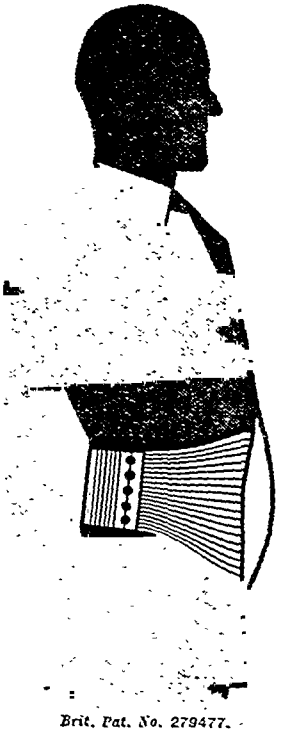
Leading Surgical Opinion approves this strong flexible support

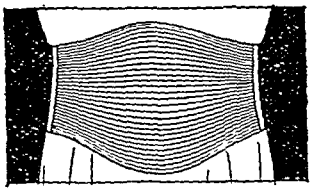


Brit. Pat. No. 279477.

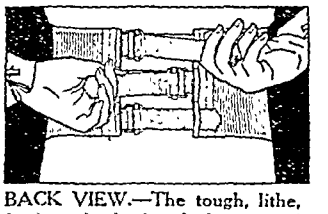
Being Pliable, it Exerts a Firm yet Natural Compression without Restriction

The Linia Belt represents a definite step forward in modern surgical belt construction, and its patented principles are widely approved by leading professional opinion.

This belt, designed by anatomical experts, is the result of 25 years' research and experiment in making elastic supports to medical requirements. The efficiency and comfort of this method of abdominal control is vouched for by the many prominent medical men who have adopted the Linia Belt for their personal use.



FRONT VIEW.—At the front of the belt the thin tricot of great strength can be extended to the required depth, so that a gentle pressure is exerted on the full area of the abdomen. Pressure is applied from pubis to groins as a safeguard against rupture.



BACK VIEW.—The tough, lithe, horizontal elastic of this special tricot can be regulated to the required tension by means of slide buckles. Thus its lifting and massaging powers are easily controlled. As the abdomen resumes its normal conformation, further adjustments of the slide buckles can be made.

THE ACTION OF THE LINIA BELT

The Linia Belt, being made entirely in an exceptionally tough elastic tricot, with firm back and strong extendible front, gives the firm and efficient support so necessary for post-operation wear *without employing any rigid components.* Thus it allows complete freedom in movement and breathing. Corpulence is reduced by a gentle massage action and a *natural* compression exerted which restores any displaced muscles and organs to their natural conformation. Recommended for post-operation wear in cases of Intestinal Ptosis, Enteroptosis, Visceroptosis, Gastroptosis, Nephroptosis.

We invite you to submit this belt to your own tests

We shall be pleased to forward a Linia Belt for your inspection free of charge. *POST ORDERS* can be carried out to your direction on receipt of exact measurement round girth and required depth from pubis upwards. Standard depths, 9, 10, and 11 inches. *Prices:* Popular Model, 2½ guineas. In black, 3 guineas. De Luxe Models, in pure silk and elastic, 5 guineas; black, 6 guineas. Standard Model, 35/-. Post free in United Kingdom.

The Linia Belt

is on sale only at

ROUSSEL, 173, Regent Street, W.1 *(Special Branch for Men's Abdominal Belts)*

M 3

ALLERGIC CONDITIONS AND PROTEIN SENSITISATION

MUCH attention has of late been directed to states in which the subject has become sensitised to some substance, and on exposure to the same substance reacts in a characteristic manner.

The substances which may sensitise are very varied (*e.g.*, animal dandruff and hairs, plant pollens and hairs, animal and vegetable proteins of foods, bacteria and their products) and the reaction may take the form of epileptic attacks, fainting fits, skin eruptions, asthma, etc.

In many instances the sensitisation is produced by bacteria or their products in the bowel, and by the exhibition of an efficient intestinal disinfectant the subject is cured. This has been found to occur in many cases of asthma, eczema and other skin diseases.

The best of all intestinal disinfectants is Kerol, which acts as a specific cure in many of these cases.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

Kerol Capsules

DISMENOL for instantaneous relief of pain in DYSMENORRHOEA

In spasmodic Dysmenorrhoea the primary call is for the elimination of pain, and the physician has a valuable weapon in Dismenol Tablets, which are entirely *free from narcotics.* This product is a sure and safe sedative in all cases of Dysmenorrhoea, possessing anti-spasmodic properties of a remarkable kind. A feeling of general well-being is substituted for the state of lassitude in the patient.

The Dual Therapeusis of MAGNESIA-OIL
(MUSTEROLE BRAND)

Attained by Clinical Experiment
Established by Clinical Trials
And abundant Clinical Evidence

M-O is definitely Laxative—it softens the contents of the colon throughout its length

DUAL THERAPEUSIS

M-O is definitely Adsorptive—inhibiting Colonic Bacteria and their toxic products

THE phenomenal state of ultra-sub-division which obtains in M-O has made possible what is unobtainable from mere mixtures of Liquid Paraffin and Magnesia. It possesses characteristics that place it in a class by itself. It is palatable, neither "leaks" nor "repeats," and does not cause either distension or a drug-habit. M-O acts upon the bowel contents rather than upon the bowel itself, thereby softening the fæces without irritating the mucosa. It is suitable for patients of all ages, and is especially valuable in gestation and pathological conditions referable to toxæmias.

N.B.—A generous Clinical Sample will be sent free of charge on receipt of your professional card.

THOS. CHRISTY & CO., 4-12, OLD SWAN LANE, LONDON, E.C. 4.

Chief Indications

Constipation of Pregnancy, Infancy, Age
Flatulence .. .. Acid Eructations
Nausea .. .. Vomiting
Hyperæmias .. .. Toxæmias
Hyper-Acidity .. .. .. Dyspepsia
Simple and Ulcerative Colitis, etc. etc.

M-O
MAGNESIA-OIL
(Musterole Brand)

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative. "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

A. WANDER, Ltd., Manufacturing Chemists,
184, Queen's Gate, London, S.W.7.

ANNOUNCING

the Issue of a New Highly-Concentrated Solution of

VITAMIN A

The Medical Research Council in their Sixteenth Annual Report draw attention to the great possibilities opened up by the recen scientific and clinical work on Vitamin A and the result obtained from the administration of large doses.

The British Drug Houses, who have for a long time manufactured and issued concentrated Vitamin A preparations, announce that, guided by these results, they have arranged to place in the hands of physicians this important anti-infective vitamin in an even more highly-concentrated form than previously, but without the admixture of Vitamin D.

The British Drug Houses will continue to issue Radiostoleum as before. This product, which has been found to yield such excellent results wherever both Vitamin A and Vitamin D are required, continues to be prescribed for prophylactic and general curative work.

The new concentrate of Vitamin A is issued in capsules. Further particulars are available on application.

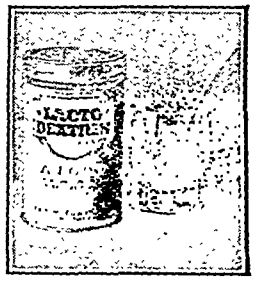
THE BRITISH DRUG HOUSES LTD. LONDON N-1

Vit.A/1

Of special service in FISSURE or HAEMORRHOIDS

"PSYLLIUM seeds when immersed in water yield a mucilaginous substance which is able to take up relatively large quantities of water to form a gelatinous mass. They become in this way a useful lubricant, while the emollient character of the mass renders it of special service in fissure or haemorrhoids."—*Lancet*, Jan. 10th, 1931.

Another preparation of importance as a laxative agent is Lacto-Dextrin—a palatable combination of lactose and dextrin for changing the intestinal flora.



Samples and literature of both these intestinal products will be sent to members of the Medical Profession on request to Coates & Cooper, 41, Great Tower Street, London, E.C.3, Sole Distributing Agents for the United Kingdom and Irish Free State.

R AND C

Specially indicated in

NEPHRITIS - URÆMIA - ECLAMPSIA - ALBUMINURIA

and allied conditions.

PROMPT and proper diagnosis of kidney conditions is necessary in cases of Bright's disease and all types of renal disorders. In nine cases out of ten the administration of a specific capable of producing real results in compensating for the loss of kidney function is also necessary.

For more than a quarter of a century Nephritin has been a sheet anchor to physicians in treating such disorders. Nephritin Tablets induce a marked increase in nitrogenous waste elimination. They reactivate the cells of the kidney, increase urinary secretion, and induce a greater output of urea.

Given in sufficient dosage these tablets produce marked results, and restoration to normal is quickly stimulated. They are invaluable also as a prophylactic in renal complications of infectious diseases and during pregnancy. The tablets are composed of the hormones of the normal kidney as they appear in nature—*absolutely unaltered.*

Samples and Descriptive Literature from Sole Distributing Agents for U.K. and Irish Free State: COATES & COOPER, 41, Great Tower Street, London, E.C.3.

WHEN THE PATIENT'S RECOVERY IS HAMPERED BY ANOREXIA . . .

these essences supply stimulus and energy without strain to the digestive system . . .

BECAUSE they are suave and non-irritant in action; because recent scientific tests have shown that they can be assimilated by the digestive organs forty minutes quicker than ordinary foods and without the formation of any residue, Brand's Essences of Beef or Chicken have come to be a preferred invalid food.

99 out of every 100 doctors, recently interviewed, recommended them in cases of intestinal disturbances, in states of exhaustion, in specific fevers, in all disorders associated with pyrexia, and before and after operations.

To-day doctors everywhere are finding these Essences indispensable in the post-influenzal state because they supply energy quickly and prepare the system to accept a more solid diet.

Brand's Essences of Beef or Chicken are prepared by an exclusive process from the finest freshly killed English meats without the addition of colouring matter or preservatives. Patients welcome them because they are delicious to taste and easy to swallow.

Samples will be gladly sent on receipt of a professional card.

Influenza and Capillary Tone

Another influenza epidemic finds us still without a specific preventive or a specific remedy. Fortunately, both the incidence and the course of the disease can be favourably modified by the observance of such rules as medical experience teaches.

It is essential to maintain vigorous metabolism and healthy capillary tone, whilst avoiding undue cold and damp. Adequate stimulation of the sensory nerve-fibrils of the skin, also, is of supreme importance in keeping the body's resisting power at its highest, and in increasing its recovery-capacity. For these purposes THERMOGENE has been found by many medical men and their patients to be convenient, cleanly and effective.

Thermogene is a carefully prepared pure cotton wadding, remarkably soft and fleecy, freed from dust and other impurities, and impregnated with skin-stimulating vegetable essences.

THERMOGENE

MEDICATED WADDING

A full-size box of Thermogene, with an interesting booklet on Surface Therapy, will be sent FREE to any medical man who is unfamilar with Thermogene and its many uses in practice.

REGETHERM POULTICE

CLEAN & CONVENIENT IN USE

More certain in action than the old-fashioned poultice

The healing action of Regetherm Antiphlogistic Poultice is governed by its ability to prolong and maintain an even degree of heat over a lengthy period. Moreover, the ingredients are so balanced that this action does not set up any counter-irritation, but allays pain, ensures an even circulation through the congested areas, and thus induces natural and pain-free rest.

The Medical Profession will appreciate the fact that the action of Regetherm Poultice is much superior to that of fomentations or linseed poultices, and can be relied upon as an efficient aid in the treatment of all types of inflammation—whether local and superficial, or of deep-seated origin.

PRICE 2/- PER 1-lb. TIN
(NOTE THE WEIGHT).

SPECIAL DISCOUNT TO THE MEDICAL PROFESSION.

Manufactured by GOEDECKE & CO., LEIPZIG (Germany)

HORLICK'S

MALTED MILK has been demonstrated to be an excellent food for the expectant mother. Pregnancy is a period when every attention must be given to the diet; extra nourishment is necessary, but *quality* is as essential as quantity. Digestive disturbances and constipation must be avoided as far as possible since they hinder the assimilation of food and lead to anxiety and exhaustion. The diet must be a simple and easily digested one, and, for many patients, modified forms of milk will be found to be more suitable than whole milk. HORLICK'S MALTED MILK is a modified milk providing the essential food elements in well-balanced proportions. It is partially pre-digested and can be absorbed by the most delicate constitutions; also its proportion of dextrin and maltose corrects any tendency to constipation, and leads to regular bowel habits. It thus ensures the efficient nourishment of the expectant mother and offspring. HORLICK'S taken at night and before rising prevents and relieves morning sickness.

(*Æsculapius*)

INJECTION TREATMENT OF

VARICOSE VEINS

Quinine and Urethane Method.

The injection treatment of Varicose Veins with a solution of Quinine and Urethane, introduced by Genevrier, gives excellent results. It is safe (no fatality after thousands of injections as yet has been recorded), it is non-toxic, non-caustic, and produces no general reaction or febrile disturbances.

VARIXOL

This is the scientifically prepared solution made at Evans' Biological Institute. It contains 4 grammes of Quinine Hydrochloride and 2 grammes of Urethane in a 30 c.c. bottle and is a stable and effective preparation. It is issued in 30 c.c. rubber-capped bottles and in ampoules of 1 c.c. and 2 c.c.

Sodium Morrhuate Method.

Sodium Morrhuate Solution is also used for the injection treatment of Varicose Veins. The effect is prompt and striking; it is harmless to the subcutaneous tissues, and very little discomfort arises from its injection.

EVANS' Sodium Morrhuate Solution 5%

is issued in rubber-capped bottles of 5 c.c., 10 c.c., 20 c.c., and 30 c.c. ampoules of 0.5 c.c., 1 c.c., and 2 c.c.

now you can give up saying "Give up coffee"

There was a time when the physician said "Give up coffee" and fervently prayed that the patient would have sufficient will-power to resist the tempting flavour and aroma of "the beloved beverage."

To-day the physician says "Give up caffein—drink H.A.G. Coffee." For H.A.G. Coffee is genuine, delicious coffee with the effects of caffein minimized. H.A.G. Coffee has two virtues that endear it to the medical profession. It can be enjoyed without danger of caffein effect. And it is so rich and satisfying in flavour that the patient is no longer tempted to drink caffein-containing coffee.

A blend of the world's finest coffees

H.A.G. Coffee is real coffee—a superior blend of the choicest Central and South American coffees. The de-caffeination process takes place *before* the coffee beans are roasted. This leaves intact all the mellow flavour and fragrance that have made coffee the world's favourite beverage. Coffee experts recognize that no other blend is finer.

H.A.G. Coffee is under the independent control of The Institute of Hygiene and British Analytical Control.

Your grocer stocks H.A.G. Coffee—ground or in the bean and in vacuum tins that preserve its freshness and its fragrance. Or send the coupon below for a liberal sample tin of H.A.G. Coffee. With it we shall be pleased to send a copy of "Some Observations of the Action of Caffein," a more complete discussion of H.A.G. Coffee. Send the coupon now.

B.M.J.2.

THE TUBERCULOSIS DANGER!

It has been stated in Parliament that *over two thousand children die every year through tuberculous milk.* How many children who survive grow up weaklings through the taint of bovine tuberculosis? This hardly bears thinking about. Cow & Gate Milk Food is guaranteed absolutely free from tuberculosis and other pathogenic organisms.

Read the following extract from the Presidential Address at the Royal Sanitary Institute Congress at Margate, it is of vital significance to the medical and nursing professions:

"The loss on the agricultural and veterinary side of 52,222 bovines during the three years 1926, 1927, 1928, slaughtered under the Tuberculosis Order of 1925, and at least twice that number not reported but otherwise disposed of, the estimate that 40 per cent. of the cows of our dairy herds producing milk for human consumption are tuberculous, are circumstances in themselves that demand immediate attention. But when to this is added the fact that in England 31.5 per cent. of tuberculosis in children up to 15 years is of bovine origin, and deaths from tuberculosis in children up to 5 years is 29.7 per cent. of bovine origin, that 57 per cent. of cervical adenitis in the same age is of bovine origin, that 33 per cent. of joint tuberculosis in children under 5 years and 24 per cent. in children from 5 to 10 years is of bovine origin, that in Scotland it is recorded that in certain hospitals in Edinburgh as much as 90.3 per cent. of cervical adenitis and 61.2 per cent. of bone and joint tuberculosis in children up to 12 years is of bovine origin, it is high time that this grave condition and this very serious menace to public health should be mended and ended. It is no credit to us as scientists and protectors of public health that such a state of affairs should be permitted to continue, or even to exist."

-IS SAFE!

Another remark made at the meeting was as follows:

'It would be better to have no milk supplied at all than to feed children on diseased milk as is being done at present.'

Cow & Gate Milk Food

COW & GATE MILK FOOD

is prepared by our Special Improved Roller Process employing a short heat treatment which destroys all disease organisms but leaves the natural vitamins unimpaired. It is a basic milk food which can be modified by the profession as they desire to suit each and every case.

HEWLETT'S
ORIGINAL PREPARATIONS.

HORMONIGEN
(HEWLETT'S)

Hormonigen Tablets (Hewlett's) contain the hormones of the thyroid, pituitary, ovary, and testes.

Useful in Neurasthenia and all asthenic conditions, obesity, chronic cardiac cases, aplasias of the pluriglandular system, and in anæmia. In Amenorrhœa, Dysmenorrhœa, and at the Menopause, Hormonigen is particularly effective, and even in chlorosis.

If there is high blood pressure, Hormonigen Sine Pituitary is indicated.

PRICE: HORMONIGEN, OR HORMONIGEN SINE PITUITARY,

3/3 PER 100; 30/- PER 1,000.

UNG. IODERMIOL

An ointment of IODERMIOL that contains about 5 per cent. of Iodine, and is, therefore, stronger than the B.P. Ointment, whilst it does not harden or discolour the skin.

It has been found most useful for Enlarged Glands, Rheumatic and Gouty Affections, Lumbago, Sciatica, Swollen and Stiff Joints, Skin Diseases, Ringworm, etc. Ung. Iodermiol has also been used in cases of burns and scalds, and in the treatment of Chronic Lymphadenitis, Simple Bronchocele, and Atrophic Rhinitis, and in Purulent Ulcerative Otitis.

PRICE 6/- PER LB.

UNGUENTUM IODERMIOL et METHYL SALICYL. (HEWLETT'S)

Useful in the treatment of Enlarged Joints, Synovitis, Rheumatoid Affections, etc.

PRICE 7/6 PER LB.

LIN. BETULAE CO.
(HEWLETT'S)

Therapeutically equivalent to several times its weight of Sodium Salicylate without causing headache, tinnitus, etc. Has proved most useful in the external treatment of pure Rheumatism, Sciatica, Lumbago, etc. The external dose is about one drachm rubbed over the affected parts.

In 5, 10, 22, 40, and 90-oz Bottles.

PRICE 10/6 PER LB.

VERONIGEN
(Formerly known as MIST. VERONAL CO.)
(HEWLETT'S)

A liquid Preparation of this prompt and reliable HYPNOTIC has long been desired as a useful means of procuring sleep. When given in reasonable doses it is claimed that it does not produce any toxic symptoms whatever, and in ordinary cases of insomnia one fluid drachm of Veronigen (Hewlett's) is quite sufficient dose for an adult.

Dose for Adults.—One fluid drachm diluted, about one hour before going to bed.

For Nervous Sleeplessness in Children.—10 to 20 minims diluted.

VERONIGEN, 10/6 PER LB.

MIST. PRUNI VIRG. CONC.
(HEWLETT'S)

A valuable stimulant and expectorant cough mixture, containing Carbonate of Ammonium, Ipecacuanha, Senega, Squill, and Syrup of Wild Cherry Bark. Quite free from Morphine, Opium, or poisons, so can be safely administered to children.

Dose: 1 to 2 drachms diluted.

In 22, 40, and 90-oz. Bottles only.

PRICE 3/3 PER LB.

MIST. TUSSI RUB. CONC.
(HEWLETT'S)

A favourite and economical cough mixture, containing Hydrobromic Acid, Chlorodyne, Dilute Hydrocyanic Acid, etc. Most successful in allaying post-influenza coughs that are so persistent. One or two ounces diluted with water to make eight ounces forms one of the most effective and elegant mixtures that can be made, and certainly the least expensive.

In 22-oz., 40-oz., 4½-lb., and 8-lb. Bottles only.

PRICE 2/9 PER LB.

Telephone: 3201 Bishopsgate (10 lines). *Telegrams*: "Greenburys Edo London."

THE 'ALLENBURYS' DIABETIC FLOUR

A special preparation of caseins and lactalbumen to which leavening agents are added.

It is a satisfactory and convenient product for the preparation of special foods, free from carbohydrates, and containing a minimum of fat; or definite proportions of these may be added as tolerance increases with the progress of the treatment. The 'Allenburys' Diabetic Flour is convenient to use, and keeps well. From it may be prepared a variety of palatable and highly nutritious foods of special composition. Recipes and directions for use are enclosed with each packet.

Further particulars and clinical trial sample will be sent on request.

Remarks
ON
ACIDOSIS FROM THE CLINICIAN'S POINT OF VIEW*

BY
LEONARD FINDLAY, M.D., D.Sc., M.R.C.P.
PHYSICIAN, EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL

I have selected the topic of acidosis because it is a subject which has become in recent years of considerable importance in explaining the pathogenesis of many pathological conditions, especially those occurring in the early years of life. To my mind there has been, and still is, much loose thinking and talking about the matter, because there is little evidence of a definite nature to support many of the opinions expressed.

Broadly speaking, acidosis may be looked upon as a disorder of metabolism accompanying many diseased processes. I would compare it in this respect with fever. In both, the disturbing factor, acid in the one case and heat in the other, is produced under normal conditions, and the abnormal state results from a disturbance of the balance between production and loss. It cannot be too strongly stated that in neither case have we got to the root of matters by merely recognizing an increased accumulation of acid or of heat in the body. We are only detecting the general results of disordered action of the tissues, which is in no way pathognomonic of any particular diseased process, though there may be variations in degree and in type in different diseases. Hence to raise acidosis to the position of a clinical entity, far from being an advance in the classification of disease, as some writers would appear to think, is as retrograde a step as it would be to classify disease according to the presence or absence of fever. Testing for acidosis is, like taking the temperature, of help in deciding if there is any evidence of abnormal action of the tissues, and probably therefore of active disease. Good comparable examples of the value of the thermometer and of the test for acetonuria are tuberculosis and diabetes.

I admit that we may be forced occasionally to a diagnosis of febricula, but it is a confession of our ignorance, and a diagnosis of which, I think, we are always ashamed. In the same way a diagnosis of acidosis should be equally guarded against. It may sometimes be the only abnormality detectable, but that does not mean that we understand what is wrong with the patient. Our predecessors frequently spoke of death from hyperpyrexia when the temperature of the body was above a certain level, but hyperpyrexia as a cause of death is seldom heard of to-day, because it is known that it is not a means of differentiating one type of a particular disease from another, far less different diseases from each other. Nevertheless, it is found advisable in treatment to try to prevent the heat of the body from rising above a certain level, and it is without doubt equally advisable to control the accumulation of the acid elements in the blood and tissue juices, because the tissues have their optimum activity at a certain definite temperature and a certain definite reaction of the blood and of the fluids which bathe them.

Meaning of Acidosis

What do we really mean by the term acidosis? It must be appreciated right away that a true acid state of the blood never occurs in life. The circulation of a free acid (that is, one not combined with its equivalent amount of base) is impossible with the exception of carbonic acid, which is the only free acid found in blood, whether normal or pathological. Of the total carbonic acid in the blood, only one-twentieth is normally present in the free state, the remainder being combined with alkali. The ratio between the free and combined carbonic acid is the ultimate factor in determining the reaction of the blood. The circulation of free acid (other than carbonic) or a really acid reaction of the blood is incompatible with life. What we understand by acidosis is a tendency to the production of such a state if matters were allowed to go on uncontrolled. The symptoms of the condition, as well as the tests available, are evidence of the means the body adopts to hinder this from coming about.

Acid is always being produced in the body as a result of katabolic activity, but its neutralization and excretion are provided for through the activity of the transport organ (the blood) and the excretory organs (lungs and kidneys). So long as this production of acid remains within normal limits, and the organs engaged in its removal are healthy, there is no evidence of any disturbance. When, however, the production of acid is excessive or pathological in amount, or abnormal or pathological in kind, the efforts of the body must be increased. Further, if the organs employed in the removal of these acids are diseased, not only will the difficulty experienced in their elimination appear earlier, but it will be proportionately greater, as in the case of a diseased heart. It is again a question of balancing the loss with the production, for the body will avoid at all costs the production of a too acid tissue plasma. Signs and symptoms are commensurate with the difficulty encountered in keeping the acid tide under way, and the task may be more than the body can perform. It is probably for this reason that there is the greatest difference between the effects of acidosis arising during the course of a disease and that experimentally or even therapeutically induced. In both, the chemical tests may reveal in equal degree the methods adopted by the body in coping with the rise in the acid tide, but symptoms are noticeably absent when acidosis is experimentally induced and the organs are apparently healthy.

THE ROLE OF THE BLOOD IN CONTROLLING ACIDOSIS

It has already been stated that no free acid can circulate in the blood except CO_2. All other acids must be combined with base. It is also a fundamental law that the total acid and basic elements which go to form the reaction of the blood are practically constant and perfectly balanced with each other. So far as the acid elements are concerned, therefore, a certain definite amount only can be carried; if some abnormal acid is present, or if one of those normally present is increased in amount, it will only be at the expense of and by replacing so much of one of the others—usually CO_2, since it is the most volatile acid: hence the indication of an increased formation of acid in the body, and of a tendency to the production of a more acid reaction of the blood and tissue juices, is a low CO_2 blood content. It is on account of the lessened power of the blood to carry CO_2, and the consequence that a larger proportion is free, that the respiratory centre is stimulated to a greater activity, with the resulting characteristic symptom of hyperpnoea. It must be appreciated, however, that a low CO_2 blood content does not always indicate a tendency to the production of a more acid state of the blood. It depends entirely on how the diminished CO_2 content is produced. In the above example the reason for the low CO_2 content is that some other acid has in part replaced it. If, however, the diminished CO_2 content results from a more rapid loss of CO_2 than normal, if it is, as it were, pulled out and not pushed out—for example, by forced

* Introduction to discussion at the Leeds and West Riding Medico-Chirurgical Society, January 9th, 1931.

respiration, which may be performed voluntarily, or as the result of high altitudes (mountain sickness), or in consequence of the hyperpnoea, which is at times a manifestation of encephalitis lethargica—then the primary change is a loss of normal acid, and the tendency will be towards the production of a more alkaline blood—the state of so-called alkalosis. This will tend to be rectified by an increase in some of the other acid elements in the body, the chlorine or organic acids. In fact, we know that in alkalosis produced at high altitudes from the loss of CO_2, and in the alkalosis found in pyloric stenosis due to a diminution of the chlorine, acetonuria does occur, this being significant of an increased formation of the organic acids of the oxybutyric series. Surely this should give the death blow to the current opinion that the presence of acetonuria indicates acidosis. Acetone in the urine simply results from incomplete combustion of fats, and may be present both in acidosis and in alkalosis. In the former it is the primary change producing a rise in the total acids, whereas in the latter the formation of excess of ketone acids, probably the result of defective oxidation, makes up for a deficiency of acid, and so helps to bring the reaction from the alkaline side back to normal.

Thus we are studying by our tests the different directions in which these abnormal changes in the blood are brought about, and the methods of the body in rectifying or compensating for a loss or an increase in the acid elements, rather than the true reaction so far as acidity and alkalinity are concerned. It is apparent, too, that for a true reading of the condition a knowledge of the factors leading up to the change—that is, the clinical history—is essential.

EXCRETORY FUNCTION OF LUNGS AND KIDNEYS

This so-called "buffer action" of the blood, which comprises a complex physico-chemical mechanism involving practically all the constituents of the blood, is not the sole means of the body's protection, since the excretory functions of the lungs and kidneys, and probably intestines also, play an important part. Excessive amounts of CO_2 are got rid of by the lungs; this may be revealed by the characteristic hyperpnoea of acidosis. The volatile acids of the oxybutyric series are also in part expelled by the lungs, and consequently we have another characteristic symptom, the smell of acetone in the breath. By the kidneys there is increased acid excretion, increase in ammonia formation to aid in the excretion of acids and to neutralize tissue juices, increase in fixed base excretion—for example, Ca from the bones and Na and K from the tissues generally—and, as it is the salts of the body which in great part retain fluid, this resulting diminution in their amount allows of the escape of fluid. In view of this function of the lungs and kidneys in rectifying any tendency towards the production of a hyperacid blood and plasma fluid, the importance of the health of these organs is apparent.

EXAMPLES OF ACIDOSIS IN DISEASE

I shall now attempt to explain how acidosis is produced in several clinical states with which we are familiar. This will be helpful, not only in fixing in our minds the more or less theoretical considerations outlined above, but in applying a sane therapy.

Gastro-enteritis

In fatal cases of gastro-enteritis a state of acidosis is often observed. This arises both from the increased production of acid in the body and an increased loss of base available for its neutralization. The former is due to the necessary concomitant starvation in consequence of the vomiting and defective absorption from the gut, apart altogether from any therapeutic deprivation of food; the latter accompanies the loss of fluid by vomiting and diarrhoea. The acidosis in gastro-enteritis is merely an indication of the severity of the lesion, and is in no way concerned with an explanation of the etiology of the condition. Nevertheless, it shows how the fatal termination may be contributed to, and it certainly suggests that the rational treatment is to replace the loss of fluid and to hinder the production of acetone bodies by the administration of water, salts, and glucose. This should be done at all costs; if they cannot be retained in the usual way, they must be administered either by the venous or the peritoneal route.

Diabetes Mellitus

Diabetes mellitus is of course the classical example of a disease in which a state of acidosis results. Owing to disease of the pancreas the patient is unable to utilize or combust sugar, and so fats are incompletely burned with the production of ketones (the acetone series). These bodies accumulate and compete with the CO_2 for the available alkali of the blood. This results not only in a diminished amount of CO_2 per unit of blood, but in a relatively increased proportion being in the free state—hence the hyperpnoea. In diabetes there is another factor working in the same direction. In consequence of the diuresis there is a washing out of the fixed alkali (Na, K, and Ca) available in the body for neutralizing the increased formation of acid. The kidney itself, however, plays an important part in minimizing this loss of base by a great increase in the formation of ammonia, which to a large extent takes the place of the fixed alkali. It is well known that renal disease increases the gravity of diabetes mellitus, and it is probable that the impaired formation of ammonia is the serious factor.

Nephritis

It is appropriate that nephritis should be considered as a disease contributing towards acidosis, since it is an example of interference with the normal excretion of the acid products formed during the processes of metabolism rather than of the production within the body itself of increased or abnormal acid. In importance or in degree, however, the acidosis produced in this way falls far behind that mentioned above.

IMPORTANCE OF HEALTH OF THE TISSUES

To illustrate the importance of the excretory organs in hindering a progressive acidosis, and to indicate the complexity of the whole problem, it is interesting to consider acidosis artificially induced, as not infrequently happens for therapeutic purposes. A state of acidosis may be induced by adding to the body one of its acid elements—chlorine—or by encouraging the incomplete combustion of fat with the production of ketones.

1. The first type of acidosis may be produced by the administration of either $CaCl_2$ or NH_4Cl. In the case of the former drug the Ca is split off in the gut and the Cl alone is to all intents and purposes absorbed. In the case of NH_4Cl the ammonia factor is converted into urea and leaves the Cl free. In both instances the chlorine content of the blood rises and competes with the CO_2 for the available base. Thus in both instances there is a fall in the CO_2 content of the blood, which, with certain provisos, is not only our evidence, but also our measure of the degree of acidosis.

2. In the second type of induced acidosis the incomplete combustion of fat with the production of ketones is brought about by the withdrawal of food (starvation), or by disturbing the balance of fat and carbohydrate in the diet (poor carbohydrate and rich fat). In this case the acetone bodies (ketones) compete with the CO_2 for the alkali of the blood and tissue juices, and again the CO_2 content of the blood is diminished.

It is a striking fact, however, that although by estimation of the CO_2 content of the blood in either of these two types of acidosis there might appear to be a degree equal to that met with when the condition arises spontaneously, yet no symptoms are apparent. It is admitted, of course, that if the doses of the salts of chlorine are enormous, symptoms do arise, but I have seen as severe an acidosis, at least as revealed by CO_2 content of the blood and the amount of acetone in the blood and urine, induced by a ketogenic diet as in many an example of gastro-enteritis or of cyclical vomiting, but I have never seen vomiting and hyperpnoea. Moreover, almost always within a day or two, in spite of a continuation of the ketogenic diet or administration of the drugs ($CaCl_2$ and NH_4Cl), the degree of the blood changes becomes modified. This brings home to us the remarkable powers of the body in accommodating itself to new conditions, and the completeness of these powers so long as the tissues are healthy. It also demonstrates that the symptoms of acidosis, and the progressive and cumulative nature of the condition as met with clinically, are not so much due to any peculiar pathological process as to the inability of the tissues, in consequence of the effect of disease in general on the cells, to exert their inherent regulating mechanism.

THE TREATMENT OF GASTRIC AND DUODENAL ULCER

A STATISTICAL INQUIRY

BY

A. RENDLE SHORT, M.D., B.S., B.Sc. F.R.C.S.

SURGEON TO THE BRISTOL ROYAL INFIRMARY

It is useless to discuss the prognosis and end-results of the treatment of these ailments unless there is a clear understanding of what we mean by the terms in question. There was a time, up to, shall we say, 1910, when it was generally supposed that a patient with haematemesis, with or without other symptoms, had an ulcer, and that many patients with intractable dyspepsia had either ulcer or "gastritis." Needless to say, any conclusions as to the value of medical treatment derived from those days are not trustworthy. Then we learned that haematemesis without pain was seldom, if ever, due to an ulcer, or at any rate to an ulcer that a surgeon could demonstrate, but was the result of bleeding from multiple gastric erosions, or, less often, from a single soft acute ulcer. Haematemesis with pain did not necessarily mean peptic ulcer; it might be associated with a tiny, withered-up appendix. Again, it was thought that hunger-pain meant duodenal ulcer, but many fruitless operations revealed that this was also misleading; hyperchlorhydria, often of reflex origin, might give this symptom without any ulcer. There was an unhappy period—up to 1920, or a little after—during which we were all at sea with regard to the diagnosis of gastric conditions; our methods were inadequate, and we no longer believed, as we had done before surgery taught us otherwise, that gastric or duodenal ulcer could be recognized with certainty. In this period, therefore, we get little or no help towards reading the natural prognosis of peptic ulcer, or the end-results of medical treatment. Shortly after 1920, methods of *x*-ray examination were worked out, perfected, and came into general use, and the study of symptoms and of chemical analyses made advances, so that now the diagnosis can be made with reasonable accuracy, and often with absolute certainty. The time has come at last, by using the material collected since 1920, to form some conclusions as to the prognosis.

RESULTS OF MEDICAL TREATMENT

That cases of gastric ulcer, even when deeply adherent, can and do heal, either spontaneously or with medical treatment, is certain, partly on clinical, partly on post-mortem evidence, the scars being found at necropsy. According to Stewart, 5 per cent. of the cases examined in the post-mortem room at Leeds showed open or healed gastric ulcers. Simple pyloric stenosis nearly always indicates the presence of an ancient healed duodenal ulcer, just as hour-glass stomach means an ancient healed gastric ulcer. It is also certain that chronic gastric and duodenal ulcers, untreated or treated, may lead to fatal haemorrhage or perforation, and that these catastrophes are not infrequent. They are nearly always the result of chronic, not acute, ulcer. Lord Moynihan and Stewart found over a period of twelve years that of 61 cases of fatal perforated gastric ulcer, 60 were chronic ulcer and 1 was acute; of 14 cases of gastric ulcer with fatal bleeding, 13 were chronic ulcer and 1 was acute; and that of 117 cases of fatal perforated duodenal ulcer, 109 were chronic ulcer and 12 were acute. Acute and chronic ulcers were found in 4 cases.

Of 100 cases of chronic peptic ulcer there is no reliable evidence to indicate how many would heal, or bleed, or perforate. At Leeds, out of 96 cases in which death was attributed to gastric ulcer, 68 had perforated; this had occurred in 178 out of 200 cases due to duodenal ulcer. On the other hand, of 164 patients treated at New Lodge Clinic for gastric or duodenal ulcer between 1921 and 1927, only 3 are *known* to have perforated. The majority of these 164 cases have a long history; cases of perforated ulcer usually give a history of less than a year, so that the true incidence of perforation must be higher. It is the anterior ulcer that perforates into the general peritoneal cavity, whereas the long-standing ulcer is usually on the lesser curvature or posterior wall. According to Hurst, Moynihan, and Balfour, about 20 to 25 per cent. of cases of gastro-duodenal ulcer bleed. At Guy's Hospital, during the period 1911 to 1920 (Conybeare), 600 cases of haematemesis were admitted, and the mortality was about 2.5 per cent. Crohn of New York gives 94 cases treated medically, with 4 deaths; but Bulmer, at Birmingham, mentions 526 cases with 67 deaths, or 12.7 per cent.

In regard to recent statistical evidence relating to the results of medical treatment for gastric and duodenal ulcer, the following studies are available. The medical treatment adopted was, generally speaking, rest in bed, a milk diet, and alkalization.

Einhorn and Crohn, writing in 1926, present the results of a careful follow-up of 100 cases. One year after treatment, 67.5 per cent. were cured, and 22 per cent. were better; four years after treatment, 27 per cent. were cured, and 23 per cent. were better. Their statistics show very little difference between gastric and duodenal ulcers.

David Smith gives the immediate results in 214 cases treated between 1913 and 1922 as follows: 67 per cent. of the males "cured," 2 per cent. dead; 76 per cent. of the females "cured," 5 per cent. dead. In cases observed five to fifteen years later, 29 per cent. of the males were "cured," 19 per cent. were dead; while the corresponding figures for females were 40 per cent. and 15 per cent. The percentages were calculated on the original number of cases.

Forman, at Guy's Hospital, studying a series of 41 cases five years after treatment, found 22 per cent. of the patients well, 20 per cent. better, and 57 per cent. no better. Franklin White, in a series of 206 private cases followed up from three to five years, reported that 30 per cent. of the gastric patients were well and 24 per cent. better; while 57 per cent. of the duodenal patients were well, and 21 per cent. better. Of the gastric cases,

42 per cent. of the patients came to operation, and 4 died under medical treatment; of the duodenal cases 4 per cent. of the patients were no better, and 18 per cent. came to operation.

Barford, studying the late results of all the 160 cases treated at the New Lodge Clinic since 1921 (the diagnosis therefore being as accurate as possible), found that of the gastric cases (about 30) 39 per cent. were quite satisfactory, 13 per cent. fairly good, and that one-third had relapsed. Of about 130 duodenal cases, 41 per cent. were very satisfactory, 28 per cent. fairly good, and there was recurrence in 24 per cent., about half of these being ultimately operated upon. R. Hutchison comments: "Considering that these results were obtained in private patients treated under the best conditions, they must be regarded as disappointing."

Enthusiastic physicians often claim that they can see large deep gastric ulcers heal in a few weeks under *x* rays. There is a serious fallacy here. Large, deep ulcers on the leg do not heal so readily; why should gastric ulcers? After a jejunostomy for an ulcer too big to resect, months or years are necessary before it heals. I have myself operated on cases of ulcer supposed to have healed as shown by disappearance of the crater in the skiagram, and found the ulcer as large as ever.

The principal factor determining the probability of cure in any particular patient is the duration of symptoms. Nielsen believes that if relapse is going to take place it will nearly always occur within two years; he therefore made a study at the end of two and a half years after medical treatment, to see how patients with ulcers of various durations had fared. The results are given below.

Duration of Symptoms	Cured (per cent.)	Better (per cent.)
6 months	60	17
½ to 1 year	54	17
1 to 3 years	37	21
3 to 5 years	20	27
5 to 10 years	11	11
Over 10 years	5·3	17.6

We conclude, therefore, that given the best medical treatment, three out of four cases of gastric or duodenal ulcer, probably more, will become symptom-free. Only 40 per cent. of the patients will remain well, and from 15 to 19 per cent. will be dead in about ten years. Early cases do well, long-standing cases badly.

Obviously, every patient without mechanical obstruction ought to have a fair trial of medical treatment, but it is also clear that there comes a time when surgery is called for in a substantial minority of the patients.

RESULTS OF SURGICAL TREATMENT

We are, fortunately, in possession of unusually reliable information on this subject, thanks to the report drawn up by a physician, Dr. Luff, of the Collective Investigation, by the British Medical Association, into the After-History of Gastro-enterostomy, published in 1930.

Reports of 2,609 operations, performed by 86 surgeons—the after-results being for the most part reported by the family doctor—were sent in. These should at least be fair, and represent the work, not of a few picked surgeons, but of the rank and file—as seen not by themselves, but by others. Besides, the records are not vitiated by too early reporting; the operations were performed between the years 1920 and 1924, and the figures were collected in 1928. The general results may be gathered from Table I.

TABLE I.—*B.M.A. Collective Investigation: After-History Results of Gastro-enterostomy*

	Duodenal	Pyloric	Gastric Ulcer	Hour-glass Stomach
Cases	995	451	533	65
Males	83.6%	72.4%	66.2%	15.4%
Females	16.4%	27.6%	33.8%	84.6%
Operative mortality	5.0%	2.6%	8.9%	12.3%
Good recovery ...	91.5%	95.4%	90.5%	84.6%
Delayed recovery ...	3.5%	2.0%	0.6%	3.1%
Results.				
Very good ...	67.2	76.3	74.3	83.7
Good	22.3 } 89.5%	16.2 } 92.5%	16.1 } 90.4%	7.0 } 90.7%
Fair	5.1%	4.1%	5.4%	7.0%
Poor	5.4%	3.4%	4.2%	2.3%
Secondary gastro-jejunal ulcers	2.8%	0.9%	0.8%	—
Secondary haemorrhage	2.4%	1.2%	1.0%	—
Secondary haemorrhage fatal	0	0	0	—
Post-operative cancer	0	0	2 doubtful cases	—

As Lord Moynihan pointed out, the term "pyloric ulcer" is not a very satisfactory one; probably these ulcers are nearly all of duodenal origin. It will be observed that for both gastric and duodenal ulcer the good results are about nine out of ten, and the failures 5 per cent. The alarmist statements of certain Americans as to the frequency of gastro-jejunal ulcer are discounted; it was recognized only in 3 per cent. of the duodenal cases, and in 1 per cent. of the gastric cases. There was no known instance of secondary cancer among the duodenal and pyloric cases, and only two, both open to doubt, after gastric ulcer. Diarrhoea was reported to be slight in about 5 per cent., and severe only in 0.5; constipation was commoner. Patients returned to work within three months in 73 per cent. of the duodenal cases and in 75 per cent. of the gastric; more than 90 per cent. were able to return to full work.

Lord Moynihan has analysed the figures to determine the difference between a mere gastro-enterostomy and a gastro-enterostomy combined with removal or infolding of the ulcer (Tables II and III).

TABLE II.—*Percentage Mortality According to Treatment*

Operation	Duodenal Ulcer	Pyloric Ulcer	Gastric Ulcer
Gastro-jejunostomy with removal or infolding of ulcer ...	1.8	1.3	4.6
Gastro-jejunostomy only... ...	5.7	2.5	11.4

TABLE III.—*Percentage of "Very Good" Results According to Treatment*

Operation	Duodenal Ulcer	Pyloric Ulcer	Gastric Ulcer
Gastro-jejunostomy with removal or infolding of ulcer ...	81.2	72.4	81.7
Gastro-jejunostomy only... ...	61.5	44.7	50.9

The report presents some surprises. The death rate is too high; in the best hands it is less than half that given in the report. It was generally thought that the end-results of operation for gastric ulcer, apart from big resections, were not nearly as good as for duodenal ulcer, but these figures reveal little difference, except a rather higher operation mortality.

The results of the inquiry have been criticized by physicians, notably A. F. Hurst, on the grounds that many cases were lost sight of, and perhaps did badly, and that four to eight years is not a sufficiently long period to give true end-results. This may be admitted, but the general experience is that our successes pass right away from us, and our failures hang around our necks for ever, so there is no reason to believe that the lost cases did worse than those followed up. If there is to be a controversy about end-results between the physician and the surgeon, is it not probable that a more extensive observation period will disconcert the former at least as much as the latter by bringing to light some late relapses?

Turning to the results of individual surgeons, or particular hospitals, we have to take into account the nature of the operation performed. Those coming under consideration are: gastro-jejunostomy only; gastro-jejunostomy with local excision of ulcer; pyloroplasty; partial gastrectomy.

The following tables, culled from recent publications, give representative results in England, America, Russia, Germany, Rumania, France, and Hungary.

TABLE IV.—*Mortality of Gastro-jejunostomy for Gastric and Duodenal Ulcer*

	Cases	Mortality per cent.
A. Gastric and duodenal ulcer:		
Paterson	499	0.8
Coffey	375	2.4
Solkov and Iljin	1022	3
Sawkoff	617	3.2
Schwarz: Anterior	203	20
Posterior	65	10 8
Total	273	17.5
Tanasesco	170	4
De Takats	270	5 8
B. Duodenal ulcer:		
Sherren	763	2
Walton	172	2.3
Fremont Smith and McIver (some infolding of ulcer)	393	6
C. Gastric ulcer:		
Sherren	630	4.6
Walton (+ wedge excision)	67	3
Fremont Smith and McIver (often + infolding or excision)	251	9

TABLE V.—*End-results of Gastro-jejunostomy*

A. Gastric and Duodenal Ulcers	Cases Followed	Quite Well (per cent.)	Better (per cent.)	Poor (per cent.)
Paterson	447	78	14	8
Solkov and Iljin	580*	71	3.6	2.6
Sawkoff	327	69	13	18
Schwarz	221	50	14	36
Coffey	305	73	14	4
De Takats	270	50	22	28

* Figures given do not tally. Many died of unconnected causes.

B.	Cases Followed	Better	Not Better	Died Since
Walton:				
Duodenal ulcer	157	146 (93.4%)	7	4
Gastric ulcer	66	59 (92%)	4	3

TABLE V (*continued*).

C.	Cases Followed	Quite Well	Mild Symptoms	Poor Result
Fremont Smith and McIver:				
Duodenal ulcer	261	66%	15%	19%
Gastric ulcer	151	69%	12.5%	18.5%

D.	Cases Followed	Quite Well	—	—
Sherren:				
Duodenal ulcer	500	92%	—	—
Gastric ulcer	403	78%	—	—

Gastro-jejunostomy

English surgery is represented by the writings of J. Sherren and of A. J. Walton of the London Hospital, published in 1928, and of H. Paterson, published in 1927. Sherren used gastro-jejunostomy in all cases of duodenal ulcer operated on, and in most cases of gastric ulcer; large, deep, adherent gastric ulcers were treated by partial gastrectomy. His statistics represent cases followed up for two or more years. Walton treats gastric ulcer as a routine by a wedge excision plus gastro-jejunostomy. Paterson, unlike the great majority of surgeons, practises an anterior gastro-jejunostomy by itself for both duodenal and gastric ulcers. The results relating to operation mortality are given in Table IV, and those relating to end-results, collected some years later, in Table V. It will be observed that the death rate is a good deal lower than that recorded in the Collective Investigation, that Walton's end-results are about the same, but that Paterson's and Sherren's, for gastric ulcer, are not so good, which may be attributed to leaving the ulcer behind.

Fremont Smith and McIver, writing from Boston, made a special study of the later end-results. They found that there was little difference between the gastric and duodenal cases. The proportion of poor results rose from 10 per cent. after one year, 15 per cent. after four years, to 20 per cent. after six years, but fell to 14 per cent. after ten years. Coffey also represents American surgery.

Solkov and Iljin report a huge series of Russian cases extending over many years, gastro-jejunostomy being performed almost to the exclusion of resection or excision operations. Another similar series is given by Sawkoff, also of Russia. These cases were published in 1927 and 1928 respectively. The immediate mortality was low, but the end-results poor, with many deaths from unconnected causes. This is not surprising in view of social conditions in Russia. German figures, given by Schwarz of Rostock, are truly dreadful, and can scarcely represent the best surgery in that country. The operation mortality at Jassy (Rumania), given by Tanasesco in 1928 (rather complicated by the inclusion of a certain number of resections, etc.), is much the same as in England, as are the French results published by Gosset and Loewy (also mixed with a few resections).

De Takats of Budapest shows a death rate of 5.8 per cent., but agrees with other Central European surgeons that the end-results are bad; only half the patients are really well, and in 28 per cent. the sequel was disappointing. It may be that food habits in America and on the Continent are more conducive than those in the British Isles to recurrence of ulcer symptoms, but there is a strange difference, which can scarcely be due to varying methods of appraising the results, between the 25 per cent. of bad results abroad, as compared with only 5 per cent. *in this country. Balfour, at the Mayo Clinic,* has published the end-results of gastro-jejunostomy in 100 doctors suffering from duodenal ulcer. There were 90 who were

quite well, 5 better, and 5 no better—a singular resemblance to the British figures.

Pyloroplasty

For many years at Finney's clinic it has been maintained that pyloroplasty is a more physiological treatment for gastro-duodenal ulcer than gastro-enterostomy. The comparative results, for a series of patients operated on between 1900 and 1925 at the Johns Hopkins and Union Memorial Hospitals, were found in 1929 to be as follows:

TABLE VI.—*Results following Gastro-enterostomy and Pyloroplasty for Duodenal Ulcer*

	Gastro-enterostomy	Pyloroplasty
Number of cases	95	139
Died within six months	16 (16.6%)	8 (5.8%)
Not traced	15	25
New total	65	106
Living:		
Improved	54	91
Unimproved	4	11
Dead:		
Causes related to original condition ...	2	0
Causes unrelated to original condition ...	5	4
Improved by operation	59 (90 8%)	95 (89.6%)
Not improved by operation	6 (9.2%)	11 (10.4%)

It will be observed that, as far as the end-results are concerned, the benefits of gastro-enterostomy and of pyloroplasty are practically identical, but that at this clinic there is a high post-operative mortality, mostly from obstruction, after gastro-jejunostomy. This does not accord with the experience of others (see the figures of the British Medical Association Inquiry).

Resection Operations

The large proportion of poor end-results, and certain theoretical considerations, have led most of the prominent American and Continental surgeons, and some British, to advocate big resection operations for both gastric and duodenal ulcers. It has been maintained by Lewisohn, for instance, that gastro-jejunal ulcer, a most unpleasant complication which usually needs a second serious operation and even then may relapse, follows gastro-enterostomy for duodenal ulcer in as many as 34 per cent. of the cases, in his experience. English surgeons put it at less than 4 per cent. Digby Chamberlain, searching the records of Lord Moynihan's cases over twelve years, reported after a two-year interval that he had found 1.8 per cent. of gastro-jejunal ulcers. Walton admits 3.4 per cent. Sherren had 29 cases of secondary ulcer out of 903 followed up for two years or more (0.4 per cent.). I do not know of a case following my own gastro-duodenal operations, though I have treated a good many patients who had been operated on by others. The B.M.A. Collective Inquiry brought to light 2.8 per cent. of cases of gastro-jejunal ulcer after an anastomosis operation for duodenal ulcer.

More serious even than gastro-jejunal ulcer is gastro-jejuno-colic fistula, which is usually fatal in spite of treatment. Fortunately it is quite rare. Only two cases, both originally operated on elsewhere, have come under my care.

There has been some difference of opinion as to the frequency with which a carcinoma may develop in an old ulcer of the stomach. According to Wilson and McCarty of the Mayo Clinic (1910), 71 per cent. of their cases of cancer of the stomach started in ulcer, and 68 per cent. of the resected ulcers showed commencing malignant changes. Obviously, if this were true, gastro-jejunostomy without excision of a gastric ulcer would more often than not be followed by the development of a cancer, and resection ought to replace short-circuiting. This is contrary to all sound experience. It is true that, at the same clinic, Balfour found that there was a rather high death rate during the first few years following gastric operations—three times that of the general population—and in 40 per cent. these deaths were due to cancer. On the other hand, most pathologists discount the theory that there is a very great risk of cancer in cases of gastric ulcer. Stewart of Leeds found that of 70 cancers, 11 (or 15.7 per cent.) arose in ulcer, and of 180 chronic ulcers resected, 11 (or 6 per cent.) showed cancer in the margin. Most surgeons, myself included, have seen cases of ulcer excised which unexpectedly displayed early cancer on histological examination; and, again, most surgeons have seen a few, but only a few, of their patients with gastric ulcer treated by gastro-jejunostomy return with a cancer. The figures published are as follows: Paterson (1914) 1 per cent.; Rehfuss (1924) 1.2 per cent.; Exalto (1918) 2 per cent.; Anschutz and Konjetzy (1920) 3.3 to 6.9 per cent. In the B.M.A. Collective Report there were only 2 cases among 538 followed up, and both of these were doubtful. Cancer never develops on the site of a duodenal ulcer.

We may conclude, therefore, that a simple gastro-jejunostomy may be followed by gastro-jejunal ulcer in about 4 per cent. of the cases, and by cancer in, say, 2 per cent. If the surgeon contented himself with a mere anastomosis, even in cases of thickened and adherent ulcer, the latter figure would probably be nearer 10 per cent.

Turning now to the results of partial gastrectomy for gastric ulcer, recent publications are summarized in the appended tables. The B.M.A. Collective Report is here somewhat misleading; only 101 gastrectomies are included, with a death rate of 6 per cent. (which is very reasonable), but only 63.6 per cent. showed "very good" results. Lord Moynihan remarks that he himself had had far more gastrectomies than 101, with excellent end-results.

English surgery is represented by Garnett Wright, Morley, and Lake, whose mortality figures vary from 3 to 9 per cent. Bastianelli of Rome has lost only 1.5 per cent. Louria, reporting from von Haberer's clinic at Graz, Austria, records 150 cases resected by the Billroth I method, with 6 per cent. of deaths, and 134 by the Billroth II method, with 11 per cent. In Finsterer's clinic at Vienna, of 175 resections for gastric ulcer, 4 per cent. of the patients died; and of 357 resections for duodenal ulcer, 2 per cent. died. Schwarz of Rostock has again a high mortality, 18 per cent., and de Takats of Budapest reports 226 cases with 5.4 per cent. of deaths. The general mortality, then, in good clinics, is from 4 to 10 per cent.

TABLE VII.—*Mortality of Resection Operations for Gastric Ulcer*

	Cases	Mortality (per cent.)
Garnett Wright	62	4
Lake	65	9
Morley: Pólya method	47	6
Schoemaker	68	3
Bastianelli	137	1.5
Schwarz	210	13
Von Haberer—Billroth I	150	6
Billroth II	134	11
Finsterer	175	4
De Takats	226	5.4

TABLE VIII.—*Results of Resection Operations for Gastric Ulcer*

	Cases Followed	Excellent (per cent.)	Fair (per cent.)	Poor (per cent.)	Died Since (per cent.)
Morley	82	74	12	5	9
Lake	51	98	—	2	—
Garnett Wright	44	75	13	2	8
Friedemann—Billroth I	221	78.5	17	4.5	—
Billroth II	153	80	15	5	—
De Takats	226	84	10	6	—
Schwarz	161	90	7	3	—
Von Haberer	54	83	17	—	—

The "follow-up" works out as follows. The three English authors have 75 to 98 per cent. of "excellent" results, and 2 to 5 per cent. of failures. De Takats and Schwarz have 84 to 90 per cent. "excellent," and 6 to 3 per cent. poor. Friedemann finds no difference between the end-results after Billroth I and Billroth II operations; both give about 80 per cent. of "excellent" results, and 5 per cent. of failures. In von Haberer's clinic, also, the perfect results are about 83 per cent. We may summarize the whole by regarding 80 per cent. as perfectly well, and 5 per cent. as unrelieved.

Comparing these figures with those of gastro-jejunostomy, with or without excision or destruction of the ulcer, the confident claims that have been made out for better end-results following resection seem to lack proof. The mortality is much the same as that given for gastric ulcer in the B.M.A. Report on gastro-enterostomy; the failures are about the same, and over against 80 per cent. of "excellent" results after resection, we have 74 per cent. "very good" and 16 per cent. "good." In expert hands, of course, the death rate after gastro-enterostomy is less, say 3 per cent. Admittedly, on the Continent and in America, gastro-jejunostomy has been much less successful.

There is, however, another aspect of the question to be considered. It is well known that patients with pernicious anaemia have usually an underlying achlorhydria. It has been stated by A. F. Hurst and others that an artificial achlorhydria induced by removal of the acid-bearing area of the stomach occasionally induces a grave anaemia. One such case has occurred in my own practice. The matter has been investigated by Gordon Taylor and collaborators, and also by Morley. In the series of 52 gastric resections investigated at Gordon Taylor's clinic some degree of secondary anaemia was found in 44 per cent., but it produced no symptoms. Of Morley's 115 cases, 16 were found to have become anaemic (that is, haemoglobin below 60 per cent.). He concludes that the Pólya operation carries with it a serious liability to future anaemia; with the Schoemaker method this is less marked.

The special danger following gastro-enterostomy, therefore, is gastro-jejunal ulcer; and the special danger after a big resection is a serious anaemia. Occasionally, gastro-jejunal ulcer follows a partial gastrectomy (0.6 per cent. in 2,310 operations—von Haberer).

Treatment of Large Gastric Ulcers

The very large gastric ulcer, often adherent to the liver or pancreas, requires special consideration. A simple gastro-jejunostomy is not likely to cure, though quite good results are often obtained when there is a large adherent mass at the pylorus, with a deep ulcer in the middle of it. Local excision with gastro-enterostomy is difficult and dangerous for a large, deep ulcer of the posterior wall of the stomach. If partial gastrectomy is possible, it is the best treatment, especially as there is always a danger of malignancy with this type of ulcer. If it is too large for resection, the choice lies between cholecysto-gastrostomy, in the hope that the bile will neutralize the gastric juice and promote healing, and a jejunostomy to allow of direct feeding into the jejunum instead of the stomach. We have no adequate statistical evidence to enable us to judge of these procedures. According to Frenkel, the result of cholecysto-gastrostomy was good in 83.6 per cent. of 68 cases in Bogoras's clinic.

Excision of Duodenal Ulcer

A number of surgeons have tried to improve the end-results in cases of duodenal ulcer by resecting the first part of the duodenum. Many surgeons, of course, make a small incision and cut out an anterior duodenal ulcer in the course of performing a gastro-enterostomy, but this is a simple matter compared with resection of the first part of the duodenum.

Pannett declared that resection is possible in 71 per cent. of his cases, that the mortality is only 4 per cent., and that it cures 85 per cent., whereas in his hands gastro-jejunostomy cures only 55 per cent. At von Haberer's clinic, where a partial gastrectomy is used for duodenal ulcer, according to Louria, 8.4 per cent. of the patients died, and of 107 cases followed up, 83 per cent. were excellent, 16 fair, and 5 poor (2 developed a gastro-jejunal ulcer). At Finsterer's clinic, of 357 cases, 2 per cent. of the patients died.

At the Mayo Clinic, according to Judd and Nagel, a smaller operation has often been performed; in the first series a simple excision of the ulcer, in a later series combined with removal of the front of the pyloric sphincter. The results were as follows:

In 140 cases of simple excision of ulcer there were 4 deaths. Of 108 patients followed up, 57 per cent. were cured and 24 per cent. were better, failure resulting in 19 per cent.

Of the series of 85 cases of excision of ulcer with partial resection of the pylorus 2 patients died; and of the 58 followed up 60 per cent. were cured, 32 per cent. showed improvement, and 7 reported failure.

It does not appear that any of these results are better than those of a simple gastro-jejunostomy.

CONCLUSIONS

1. Until about ten years ago the diagnosis of gastric and duodenal ulcer, unless verified by perforation, operation, or necropsy, was so precarious that the older statistics of medical treatment are untrustworthy.

2. Spontaneous healing can undoubtedly occur, and is not infrequent. Perforation and haemorrhage are marks of the chronic rather than the acute ulcer. About 25 per cent. of cases of peptic ulcer bleed. Perforation is common in ulcers of the anterior wall and usually occurs within a year or two of the onset; only a few, under 3 per cent., of ulcers of the posterior wall, of long standing, perforate.

3. The medical treatment of gastro-duodenal ulcer, in the best clinics, gives good immediate results. At least 75 per cent. become symptom-free. Only 40 per cent. remain so. From 15 to 20 per cent. of the patients will die within ten years. If the duration of symptoms was under a year, more than half the patients remain well; over a year, far fewer.

4. Obviously, therefore, efficient medical treatment should have a good trial. Equally obviously, a considerable number of the patients ought eventually to be operated on. Mechanical obstruction, or a large, deep ulcer that may be malignant, demands early operation.

5. The mortality and end-results of gastro-jejunostomy are set forth fairly, in an adequate number of cases treated by rank-and-file surgeons, followed up for at least four years, in the B.M.A. Collective Report. The operation mortality for duodenal, pyloric, and gastric ulcer was 5, 2.6, and 9 per cent. The follow-up, for both gastric and duodenal ulcer, showed 90 per cent. of successes (75 per cent. perfect) and about 4 per cent. of failures. Secondary gastro-jejunal ulcers followed in 2.8 per cent. of the duodenal and 0.8 per cent. of the gastric cases. Subsequent cancer was rarely, if ever, reported.

6 Individual English surgeons report a lower mortality (1 to 2 per cent. in duodenal and 3 to 4 per cent. in gastric cases). End-results are about the same as in the Collective Report, except that when a gastric ulcer is not removed the cure rate is at least 10 per cent. lower.

7. Continental and American results for gastro-jejunostomy are, for some reason not well understood, far less satisfactory. The mortality is about the same as in the Collective Report, but only 50 to 70 per cent. are cured, and 20 to 30 per cent. do badly.

8. Pyloroplasty gives results very similar to those of gastro-enterostomy.

9. Partial gastrectomy is advocated, to avoid gastro-jejunal ulcer or cancer, and to obtain a larger percentage of cures. Gastro-jejunal ulcer in England follows gastro-jejunostomy in 0.4 to 3.4 per cent. of the patients operated on. Cancer follows in about 2 per cent. of the cases. After partial gastrectomy, gastro-jejunal ulcer follows in about 0.6 per cent. of cases. Some anaemia may result from an extensive gastrectomy—mild in nearly half, serious in perhaps 10 per cent.; in a few cases, quite severe.

10. The operative mortality of partial gastrectomy for gastric ulcer is from 4 to 10 per cent. Excellent results are obtained in about 80 per cent.; poor results in 5 per cent.

11. Except in cases of large, deep, adherent gastric ulcers, which call for a resection, the results of partial gastrectomy for gastric ulcer are no better than those of simple gastro-enterostomy, in spite of a doubled operation mortality. They are not as good as those of gastro-enterostomy with wedge excision of the ulcer. This apparently does not hold good on the Continent or in America, owing to the poor results following gastro-jejunostomy in those countries. The end-results of this operation on 100 doctors at the Mayo Clinic, however, accord well with the figures obtained by English surgeons.

12. In cases of duodenal ulcer, partial gastrectomy or duodenectomy gives results no better than those of the B.M.A. report on gastro-jejunostomy, and the mortality is higher. Local excision of the ulcer, by itself, gives poor results (57 per cent. cured, 19 per cent. no better). Local excision with partial resection of the pyloric sphincter is better, but not as good as gastro-jejunostomy.

13. The deductions for treatment are: (*a*) If mechanical obstruction is not present, and cancer can be excluded with confidence, efficient medical treatment ought to be given a fair trial. (*b*) If it fails, or recurrence takes place, operation is indicated. For gastric ulcer the best operation is gastro-enterostomy with local removal of the ulcer. If the ulcer is large, deep, and adherent a partial gastrectomy is often better. (*c*) For simple pyloric stenosis, gastro-jejunostomy is best. It is safe and satisfactory. (*d*) For duodenal ulcer, gastro-jejunostomy is the best treatment. If the ulcer is readily accessible it should be excised.

It is a trite saying that statistics can be made to prove anything. It may be desirable to add, therefore, that the conclusions we have drawn from our statistical study coincide exactly with my own experience of the results of medical and surgical treatment of gastric and duodenal ulcer.

CONVULSIONS DURING SURGICAL ANAESTHESIA

NOTES ON A SERIES OF CASES*

BY

J. ROSS MACKENZIE, M.D.

LECTURER ON ANAESTHETICS, UNIVERSITY OF ABERDEEN; ANAESTHETIST, ROYAL HOSPITAL FOR SICK CHILDREN, AND ROYAL INFIRMARY, ABERDEEN

The convulsions in these cases must not be confused with ether clonus. They are generalized, epileptiform convulsions, commencing in most cases on the left side of the face and rapidly affecting the whole body. The movements may become so violent that the surgeon is compelled to discontinue the operation, and in some cases the patient has had to be protected against personal injury. Seven cases have come under my observation, and the salient features which characterize this alarming and serious complication of surgical anaesthesia will be narrated.

The subjects of these convulsions were all young people. They occur at a time in life when the central nervous system is very unstable, and therefore very vulnerable. They all had a temperature and a rapid pulse. They were all suffering from an acute septic condition with general toxaemia. In two cases a haemolytic streptococcus was found in the discharge, and in one case in the blood. In the seven cases ether, unheated,[1] formed part of the anaesthetic agent during the induction or maintenance of anaesthesia, and the convulsion appeared after the operation was well under way.

Appended are brief notes of the first, fourth, fifth, and sixth cases.

The first case occurred in March, 1926. It was of special interest to me as I had, until then, never seen anything of the kind during surgical anaesthesia.

A female, aged 5, very ill with an acute abdomen. Temperature was 102.6°, pulse rate 130. Atropine sulphate

* Delivered to the Aberdeen Medico-Chirurgical Society on January 15th, 1931.

/100 grain preceded nitrous oxide, oxygen, and ether anaesthesia, with carbon dioxide during the induction. A considerable quantity of foul-smelling purulent fluid was found in the abdomen, and the appendix was removed. Suddenly, as the surgeon was about to close the peritoneum, clonic contractions commenced on the left side of the face, left arm, body, and leg, followed rapidly on the right side. The convulsion was epileptiform in character, and continued for fifteen minutes, during which time the surgeon was unable to continue the operation. The treatment consisted of cutting out the anaesthetic and of giving oxygen only. The cause of the convulsion is noted thus: query carbon dioxide, query impure ether, query toxaemia, probably a combination of these and toxaemia very important. This child made a good recovery.

The fourth case occurred in December, 1927.

A female, aged 7, with a temperature of 103°, pulse rate 160, and respiration 40. Very ill with acute osteomyelitis of left tibia and fibula. Atropine sulphate 1/100 grain preceded a simple open ether anaesthesia. The operation had been in progress fifteen minutes when twitching commenced in the muscles of the left side of the face and spread to the arms, legs, and body. The convulsion continued for eighteen minutes. On the first sign of twitching the ether was withdrawn and oxygen given through the nose. The pus from the tibia and the blood gave a pure culture of haemolytic streptococci. This child died some hours later.

The fifth case occurred in March, 1928.

This was a female, aged 3. Temperature was 101.5°, pulse rate 120. There was a scarlatiniform rash over the body, which turned out on evidence to be a septic rash. The diagnosis was an acute abdomen. Atropine sulphate 1/150 grain preceded a nitrous oxide, oxygen, and ether anaesthesia, with carbon dioxide for the induction. The abdomen was opened, and pus welled up from the region of the pelvis. The pus gave a pure culture of haemolytic streptococci. There was a considerable degree of peritonitis. While the appendix was being removed clonic contractions of both arms and legs commenced. The convulsion rapidly became generalized, and with considerable difficulty the peritoneum was closed, when the anaesthetic was discontinued and oxygen given. There was considerable respiratory distress and cyanosis. The convulsion lasted for fifteen minutes. This child made an excellent recovery.

The sixth case occurred in October, 1929.

A male patient, aged 6, with very acute abdomen. Temperature was 104.8°, pulse rate 130. Atropine sulphate 1/150 grain preceded nitrous oxide, oxygen, and ether anaesthesia. Carbon dioxide was not used. The abdomen was full of evil-smelling pus, and a gangrenous appendix was removed. Soon after the peritoneum was opened the patient became restless and dusky in colour, with slight respiratory difficulty. This was quickly followed by clonic contraction, bilateral, of the face, and quickly spread over the whole body, and continued throughout the operation. Temperature in the axilla was 108.2°; it was impossible to count the pulse rate. The respiration was laboured, and cyanosis appeared, in spite of oxygen. The temperature was brought down to 106° on the table by sponging and ice. Heroin 1/48 grain was given. Sponging continued until the convulsion ceased. The child was then put back to bed. The temperature rose to 106.8°, and convulsions commenced again. It was sponged until the temperature went down to 103.8°, and the convulsions ceased, except for twitching of the face and neck. Heroin 1/48 and digitaline 1/300 grain was given. The convulsion in this case was more or less continuous. Consciousness was never regained, and the patient died some hours after the operation.

Fortunately for the anaesthetist and the surgeon convulsions are a comparatively rare complication of surgical anaesthesia. They arise in young patients, when the nervous system is readily excited into abnormal activity by any form of toxaemia, and they have an analogy in the convulsions which occur in infants and young children as the result of reflex irritation and gastro-intestinal toxaemia.

ETIOLOGY

Many factors[2,3,4] connected with surgical anaesthesia have been challenged in an attempt to elucidate the cause of these convulsions, but there are three which call for serious consideration: (1) impurities in the ether; (2) carbon dioxide; (3) acute suppuration and toxaemia.

Impurities in the Ether

In 1926 Wesley Bourne[5] demonstrated by experiments on animals that acetaldehyde, ether peroxide, and sulphides, which are frequently present in anaesthetic ether, render ether a serious toxic agent. He showed that 1 per cent. of acetaldehyde, or 1/2 per cent. of peroxide, caused depression of the respiration and the circulation, while 1 per cent. of ethyl sulphide caused severe gastro-enteritis. In 1927 the late S. R. Wilson[6] suggested that convulsions occurring during surgical anaesthesia, of which they had had a number of fatal cases in Manchester, were due to acetaldehyde and peroxide in the ether used for anaesthesia.

Ether is formed by a process of dehydration of ethyl alcohol. The chief method of manufacture is to heat strong sulphuric acid to 140° C. and pour the alcohol into the sulphuric acid, allowing the ether to distil over into a receiver. Any undesirable ethers that may occur are purged from the final product by fractional distillation and redistillation. Diethyl ether is a fully saturated body, and should therefore be a stable body, but it contains one atom of oxygen, which renders it liable to oxidation processes when exposed to light and air, or when oxygen is passed over or through it, as occurs in using a gas, oxygen, and ether apparatus.

The impurities that occur in anaesthetic ether are: (1) Those arising from the material of its manufacture—alcohol, water, aldehyde, sulphides, sulphates, and acetone. (2) Those arising during storage and during the process of its administration and after. Organic peroxide is the first product of the decomposition of ether. It is formed by the action of light and air upon ether containing aldehyde. In the further process of decomposition of ether, organic peroxide breaks up, forming acetaldehyde, hydrogen peroxide, acetic acid, and carbon dioxide.

The presence of water in ether may give rise to alcohol, and consequently to aldehyde, by a process of hydrolysis. This is very important, since in the water sight feed gas and oxygen apparatus, water vapour is carried by the gases into the ether bottle. It is known that the chemical properties of acetaldehyde and peroxide interfere with the normal oxidation processes of the tissue cells, but whether they are ever present in high-grade anaesthetic ether to such an extent as alone to excite generalized convulsions is highly improbable.

In all my cases the ether used was subjected to expert chemical analysis, and each sample was reported to contain a minute quantity of peroxide and aldehyde. The largest amount of the former was 0.65 part per million, and of the latter 0.05 part per million. In several of the ethers there was a trace of acetone. Wilson was of opinion that 1/2 per cent. of peroxide or of aldehyde in ether was toxic.

Carbon Dioxide

The first case of convulsions occurred soon after I had commenced the use of carbon dioxide in general anaesthesia. Quite properly the question exercised my mind: Had the carbon dioxide anything to do with this convulsive state? It was certainly a new complication of which nothing was known, and there was no literature on the subject.

It was known[7] that surgical anaesthesia had been induced in animals with carbon dioxide, and, in order to

find out the effect of percentages of carbon dioxide, a series of experiments was carried out on rabbits in the pharmacological laboratory with Professor Marshall and Dr. Macdonald. All the signs of surgical anaesthesia, including muscular relaxation, were produced in the rabbit with a concentration of 35 to 40 per cent. of carbon dioxide, and quiet anaesthesia continued as long as this percentage was maintained. The rapid replacement of carbon dioxide by oxygen, or the sudden removal of the rabbit to atmospheric air, gave rise to a clonic convulsion during the recovery from anaesthesia, whereas, if the carbon dioxide was slowly replaced by oxygen, no convulsion occurred. It appeared evident that the exciting cause of the convulsion was the excessive stimulation of the central nervous system of an anaesthetized animal by the rapid inrush of oxygen.

Mennell[8] suggested that the convulsions were caused by deep ether anaesthesia and an excess of oxygen. In 1927 Pinson,[9] who had had experience of a number of cases in Manchester, considered that the convulsions were due to modern methods of anaesthesia, which tend to the accumulation and rebreathing of carbon dioxide. It must be pointed out that closed and perhalation methods of ether anaesthesia have been in general use for many years, and more recently carbon dioxide has been administered in many thousands of surgical cases without giving any clinical evidence of convulsive phenomena, while convulsions occur during a simple open ether administration.

Suppuration and Toxaemia

In all these cases an acute suppurative process with a high degree of toxaemia or septicaemia was in operation. One case had a virulent pneumococcal peritonitis, one had a haemolytic streptococcal peritonitis, and one gave a pure culture of haemolytic streptococci from the pus and from the blood. In my judgement the degree of toxaemia or of septicaemia is of the greatest importance, and forms the chief factor in the causation of these convulsions.

Ether, containing acetaldehyde and peroxide in quantities known to be many times greater than was found in the ether used when convulsions occurred, has been administered by me to non-toxic patients without any clinical evidence of convulsive phenomena.

I have arrived at the conclusion that these convulsions owe their origin to two main factors. The essential and predisposing condition is acute toxaemia, and the exciting cause is ether, itself a toxic agent, which stimulates an increased circulation of blood loaded with toxins or bacteria, or both, to the central nervous system and initiates acute cerebral irritation. The severity of the convulsion is in proportion to the virulence and acuteness of the toxaemia or septicaemia, and may be aggravated by any impurities in the ether.

PROPHYLACTIC TREATMENT

The duration of the anaesthesia would appear to be an important element. In none of the cases did the convulsion appear until the anaesthesia had continued for at least fifteen minutes. In young patients, therefore, with acute suppuration, toxaemia, and high temperature the surgeon might well merely evacuate and drain, doing the least possible until the acute phase of the toxaemia has passed. This would reduce to a minimum the period of anaesthesia, the amount of the anaesthetic agent, and the sensory stimuli from the operation area to the central nervous system.

Aldehydes and peroxides in ether have undoubted toxic properties, and tend to inhibit normal oxidation in the nerve cells. The passage of gas and oxygen over or through ether causes it to deteriorate rapidly. This is a point of considerable importance, and ether which has been used with gas and oxygen should not be used in successive cases, more especially in children with acute toxaemia and high temperature. The purest ether from a bottle opened for the occasion is the ideal.

The treatment of the actual convulsion with inhalation of oxygen was inspired by the respiratory distress and cyanosis. It appeared to benefit the patient, and 90 per cent. of oxygen with 10 per cent. of carbon dioxide[10] has been used and recommended to control the convulsion. The etiology, prevention, and treatment of these convulsions is still obscure, and demands further investigation.

Three patients have had convulsions since this article was written—two at the Sick Children's Hospital, and one, who died on the table, at the Royal Infirmary.

UNILATERAL EXOPHTHALMOS FOLLOWING ADMINISTRATION OF THYROID EXTRACT

BY

T. GILLMAN MOORHEAD, M.D., F.R.C.P.I.

CONSULTING PHYSICIAN, MERCER'S HOSPITAL, DUBLIN

The interesting point in the case reported below is the apparent production of exophthalmos by oral administration of thyroid extract, and the fact that the exophthalmos was unilateral.

Although physiologists as a body seem to agree that it is not possible to produce exophthalmos in animals by experimental administration of thyroid substance, there are some experiments on record which throw doubt on this conclusion. Edmunds[1] quotes Cunningham[2] to the effect that the latter succeeded in producing exophthalmos in rabbits by giving thyroid extract, and adds that he himself produced the same effect on whom he had given about one-half of a sheep's thyroid daily. The period over which this dose was maintained is not stated. In the same paper reference is made to the report by Béclère[3] of a case of myxoedema in which the taking of excessive doses of thyroid extract was followed by a certain degree of exophthalmos, while in the discussion that followed the reading of Edmunds's paper Lawford referred to a case seen at Moorfields Hospital in which bilateral exophthalmos, better marked on the right than on the left side, was apparently the result of the excessive administration of thyroid extract. The condition must be rare, however, and is of undoubted interest from a physiological standpoint.

Mrs. M., aged 54, who was brought to me in March, 1927, had the following history. Up to 1924 she had enjoyed perfect health, but in that year she began to feel vaguely unwell and consulted a doctor, who told her that she was suffering from myxoedema. Thyroid extract was prescribed, and immediate improvement followed. Any attempt to discontinue the extract was followed by a return of ill-health. At the beginning of 1926 the dose of thyroid extract had been increased to 12½ grains daily, and this dose was taken continuously throughout that year and up to the date of her visit to me. Early in 1927 she did not feel well, and in February noticed for the first time that her right eye was much more prominent than her left. She immediately consulted an oculist, who, after a thorough examination, assured her that there was nothing the matter with her eye or orbital tissues, and expressed the opinion that she was suffering from Graves's disease with unilateral exophthalmos. She

xt consulted a rhinologist, who told her that her nasal nuses were perfectly normal. An *x*-ray examination was rried out at this time also, and revealed nothing abnormal. inally, as already stated, she consulted me.

On examination I found that she was suffering from obvious mptoms of thyroid intoxication, with tachycardia, pulse te being 140, palpitation, extreme nervousness and restless-ss, insomnia, and loss of weight. She refused to have her sal metabolism estimated, but calculation made from the lse pressure formula gave an estimated metabolism of 118. he right eye was extremely prominent, and showed a well-narked von Graefe's sign. The left eye appeared normal. o vestige of a thyroid gland could be felt by the most careful alpation. After consideration the only possible diagnosis emed to be that all the patient's symptoms, including the xophthalmos, were due to an overdosage of thyroid extract. n consequence, the extract was stopped, and the patient was ut to bed for some time and treated with bromides. In the ourse of a couple of months the symptoms had largely isappeared, and after six months the patient was practically estored to health. As the general symptoms subsided, the xophthalmos diminished, but up to the date of my last eeing her—in June, 1928—the right eye was still somewhat nore prominent than the left.

THE SALE OF THYROID PRODUCTS

Although the object of this note is to call attention o the occasional production of ocular symptoms from hyroid administration, opportunity is taken of urging he necessity of introducing some restrictions in the sale of thyroid products. Since the earliest days of thyroid medication it has been recognized that overdosage can produce serious symptoms. These symptoms are attributed by some to the thyroid substance itself, and by others to decomposition products contained in extracts. However this may be, any physician of experience must have met with many cases in which long-standing ill-health with hyperthyroid symptoms has been caused by excess of this drug, and also certain acute cases in which sudden palpitation, giddiness, dyspnoea, and nervous terror have been brought about by prolonged overdosage. Möller, writing in the *Acta Medica Scandinavica*, has recently called attention to the subject, and suggests that thyroid substance should be put on the list of dangerous drugs. In most cases the fault lies not with the physician but with the patient. Patients learn that thyroid substance is efficacious in obesity, and without professional advice obtain thyroid tablets from a chemist, and, quite unaware of any possible harmful results, continue to take large doses for prolonged periods. If thyroid substance could be obtained only on a doctor's prescription, and that only for a limited period, the present by no means uncommon ill results could be avoided.

HALLUX VALGUS: A NOTE ON OPERATIVE TECHNIQUE

BY

PAUL BERNARD ROTH, F.R.C.S.

From a large experience of the treatment of this deformity at the Orthopaedic Department of the Miller Hospital a routine operation has gradually evolved, which has been attended by such gratifying results that a description of it may be of interest.

CHOICE OF PATIENT

Any patient who has a painful bunion over the inner side of the big toe joint, with deflection of the toe outwards, causing the second toe to override it, is judged suitable. This is the typical condition for which the patient seeks relief. Sometimes it is the unsightly appearance, sometimes the pain, sometimes the impossibility of getting shoes to fit, which sends the patient to hospital: sometimes all three together. The fact that the bunion is acutely inflamed does not contraindicate operation; it is an additional reason for it.

Age is no bar. The trouble may be present in a child aged 12 or in a man 60 or over; all react to the operation in just the same way, and are entirely relieved. Convalescence may be slightly longer in an elderly person—that is all.

The nature of the patient's occupation is certainly of influence in coming to a decision. One does not operate for choice on a person who will go back to employment which requires prolonged standing. Yet where no other work can be found, as in the case of a nurse, the operation may be performed with confidence, provided the period of convalescence is longer than usual. I should refuse, however, to operate on a toe-dancer or a professional footballer.

Women who wear high heels ask if they will be able to do so afterwards. In my experience there has never been any difficulty about this; the high heel position is always perfectly comfortable after the operation has been performed.

PREPARATION OF PATIENT

After thorough washing with soap and water, with special attention to the nails and nail folds, the feet are painted with tincture of iodine and wrapped in a sterile towel. The painting with iodine is repeated on the table. If the bunion is inflamed, the inflammation must be allowed to subside by rest in bed for two or three days. Under no circumstances is the operation performed in the presence of inflammation.

THE OPERATION

No tourniquet is used. The foot lies on its outer side, and a horizontal incision 2 inches long, parallel with the length of the toe, is made through the bunion, extending equally beyond it in both directions; it is planned to lie rather nearer the dorsum than the sole. The knife cuts down on to the neck of the metatarsal and through the layers of the bunion, exposing the head, the line of the joint, and the base of the phalanx, all in one sweep. The neck is cleared of periosteum by inserting two periosteal detachers in the line of the incision, one detaching everything above and levering it up, the other detaching everything below and levering it down. These two detachers are held with their points at right angles to each other by an assistant, and the now tense capsule is freed from the head by a few touches of the knife. Finally, the capsule is cut through vertically, opposite the joint interval, exposing the head completely. The blades of the bone-cutting forceps are insinuated above and below the neck one at a time, the detachers being separately withdrawn to make way for them, and are adjusted as close to the head as possible, with their bevelled edges turned towards it. Only the head is removed, not half an inch of the shaft as well. When the blades are in position the neck is cut through, and the severed head levered out with the closed bone-cutting forceps and the two detachers, so that it is grasped with Lane's small bone-holding forceps, twisted off, and removed. The skin edges are brought together with tissue forceps, sutured with continuous horsehair, and the operation finished by painting with iodine, inserting a gauze pad between the first and second toes, and applying a gauze dressing.

No part of the bunion itself is removed. When the patient is returned to the ward, the end of the bed is raised on 6-inch blocks, and a cradle placed over the operated foot.

AFTER-TREATMENT

This is of great importance. On the second day, strips of adhesive plaster, half an inch wide, are applied to the dorsal and plantar aspects of the big toe, and their long ends are carried up and fixed to the cross-bar of the cradle to act as an extension to pull the toe straight and make certain that there will be an appreciable space between the base of the phalanx and the cut surface of the metatarsal shaft. It is found that the patient is quite able to regulate the amount of this extension suitably by withdrawing the feet slightly up into the bed. At night the strips are undone from the cross-bar and fixed again in the morning. After four or five days the patient is shown how to pull on these strips with his hands many times in the twenty-four hours, and to assist in obtaining a straight but movable new joint. The attachment to the cradle is discontinued. After ten days the stitches are removed, but not the strips; and gentle massage to the scar is begun. In fourteen days the patient is allowed to walk in soft bedroom slippers; the strips are dispensed with altogether, and exercises are started. These consist of frequently repeated flexion and extension movements of the toes, at certain stated times every day.

In a severe and long-standing case the four outer toes have all become deflected too; these must be made to lie in their normal position again. This can be done by active and passive movements, by pulling and stretching, and by inserting small pads of gauze between the second, third, fourth, and fifth toes. Then the pressure of the slipper on the fifth toe is enough to keep all these toes straight, the malposition of the big toe having been corrected.

After three weeks the patient must be fitted with walking shoes to fit the new shape of the feet, with stout soles, ample width in the tread, and straight on the inside. Patients find a flat heel less comfortable than a moderate one, especially if accustomed to wearing a high heel. In six weeks the patient can return to work, provided it does not consist in standing all day: if it does, or if both feet have been operated on, the period of convalescence must be longer.

Massage and exercises are continued throughout the whole of this period, and at night the small pads are placed between the toes. If tenderness is complained of at first when walking, it can be relieved by binding the front part of the foot firmly with one or two encircling strips of adhesive plaster.

REMARKS

The bunion—which I take to mean all the soft parts which form over the prominent bone, consisting of a bursa, fibrous tissue, and thickened skin—is left completely alone, except for the necessary incision at the operation. It has acted as a protection for years, and had better continue to do so. What is not wanted will gradually be absorbed. If it is cut away, there is a danger of the skin becoming adherent to the bone and causing a painful scar—the last thing desired.

No artery forceps are applied. If the operation is performed quickly, say five minutes from start to finish, the periosteal detachers stop all bleeding when in position, and no ligatures are required.

The bone is cut cleanly through, subperiosteally; this means that no bone dust or splinters are left in the wound, and that a cuff of periosteum remains to cover the cut end of the shaft.

Occasionally the extensor tendons of one or more of the toes may be found contracted, and are lengthened by subcutaneous tenotomy, but this is not a routine measure. If extension is not applied, the big toe shrinks back into the foot too much (the operation always shortens the foot slightly) and may become stiff from fibrous ankylosis between the phalanx and the metatarsal shaft. Surgeons have tried to prevent this by removing some of the shaft as well as the head; but this is weakening the foot unnecessarily.

CONCLUSIONS

The important points are:

1. Cut the bone correctly.
2. Leave the bunion.
3. Apply extension.
4. Give exercises and massage.
5. Order shoes that fit the newly constructed foot.

AMOEBIC HEPATITIS WITH HAEMATEMESIS

BY

R. E. DRAKE-BROCKMAN, D.S.O., M.D.

TROPICAL SPECIALIST TO THE MINISTRY OF PENSIONS; LATE MEDICAL OFFICER, UGANDA, EAST AFRICA, AND SOMALILAND PROTECTORATE.

The following account of a case of amoebic hepatitis with severe haematemesis is worthy of record, as I have been unable to find a similar case in the literature.

A nurse, aged 40, who served for two years in Mesopotamia during the war, came under my care in 1925. The only sickness recorded during her war service was as follows: appendicectomy in August, 1916; pain in the lower part of the abdomen in January, 1918; sand-fly fever in August of the same year; anaemia and debility with abdominal pain and vomiting in September, 1919. She was invalided to England. Laparotomy was performed in April, 1920. The gall-bladder was excised and thirty-nine stones were removed. The right ovary was cystic. In August, 1920, she complained of pain in the epigastrium. Amoebic hepatitis was diagnosed in November, 1923. *Entamoeba histolytica* was found in the stools. The liver was two finger-breadths below the costal margin.

After the last diagnosis she received a disability pension in 1924, and came under my care in the following year. She had then a definitely enlarged liver, and suffered from chronic constipation. From 1925 to 1929 she remained at work at her hospital and reported to me once a month for treatment. During this time she only had an occasional "flare-up," which rapidly subsided under appropriate treatment. While under my care no *E. histolytica* cysts were found in the stools in the course of numerous examinations. Towards the end of 1929, as her health had been much the same for several years, her disability pension was made final, and I did not see her again until quite recently. In January, 1930, after having more or less acute pain in the liver for some days, she had a severe haematemesis, vomiting about two pints of blood, and melaena. She was still more or less constipated, and the stools were very pale in colour. As her condition had worsened since her pension was made final, her case was reopened for further adjudication, and I saw her again. The question had arisen whether the haematemesis could be regarded as a sequel of her invaliding disability. On examination in October, 1930, I found that she had so far recovered that her condition was much the same as it was in 1929. There was no jaundice or apparent anaemia, and no enlargement or increase in liver dullness. The heart and lungs were healthy. There was some tenderness in the epigastrium on light palpation, but no mass could be felt. The ascending colon was palpable and tender. The stool examination was negative. A complete radiological examination was made of the whole intestinal tract, and the report was as follows:

"Considerable elongation of stomach. Stomach is hypotonic. Intermittent hyperperistalsis. No evidence of gastric ulcer. Duodenal cap showed persistent deformity; the second part is pulled over to right. Deformity more suggestive of adhesions than that due to an ulcer. Marked ptosis of

xures of colon, but apart from this no definite evidence of ganic disease."

The blood count showed: red blood cells 4,500,000 r c.mm., white blood cells 8,000; polymorphonuclears 74 per nt., large mononuclears 4 per cent., lymphocytes 20 per nt., eosinophils 2 per cent.; haemoglobin 90 per cent.; lour index 1.1. No abnormal cells were seen.

COMMENTARY

The interesting point about this case is that the clinical, adiological, and microscopical examinations appear to xclude all the commoner conditions giving rise to a aematemesis of such severity. The patient stated that he had never suffered from any gastric symptoms in her fe, nor did the radiological examination show any vidence of gastric or duodenal ulcer, nor had she been reated for either at any time. There is certainly a possiility that the deformity of the duodenal cap was due o an ulcer as well as to adhesions. The past clinical istory undoubtedly points to the latter cause. At the ame time it seems incredible, if an ulcer did exist, hat it would give rise to no clinical symptoms save a udden and severe haematemesis, which did not recur and or which no special treatment was given.

There had never been any evidence of cirrhotic changes n the liver. Thrombosis of the portal vein can be liminated, as the other usual sequels—namely, enlargement of the spleen and ascites—were entirely absent, and the haemorrhage had not recurred. The normal blood count, together with a normal spleen, excluded early splenic anaemia and leukaemia. What, then, was the cause of the haematemesis? We appear to be left with a gastrostaxis occurring by diapedesis. Might this not be the result of a very sluggish liver of long duration giving rise to a more or less constant hyperaemia of the gastric mucosa? However sceptical one may be in regarding the haematemesis as a sequel of the amoebic hepatitis, it is difficult to exclude the contingency occurring in such an obstinate and long-standing case.

It must be borne in mind that the patient is a nurse on duty in a fair-sized hospital, where she has always had constant and immediate medical attention from a highly competent staff of medical practitioners, so that any gastric disturbances would have been promptly treated.

I have to thank the Director-General of Medical Services, Ministry of Pensions, for permission to record this case.

CONGENITAL ANEURYSM OF THE BRAIN

BY

HUGH REID, M.B., CH.B., F.R.C.S.

HONORARY ASSISTANT SURGEON, ROYAL INFIRMARY; DEMONSTRATOR OF SURGICAL PATHOLOGY, UNIVERSITY OF LIVERPOOL

AND

HUMPHREY H. GLEAVE, M.B., CH.B., M.R.C.P.

LECTURER IN PATHOLOGY, UNIVERSITY OF LIVERPOOL

The problems of differential diagnosis are nowhere more strikingly illustrated than in aneurysms of the base of the brain. It is now well recognized that besides those instances in which the condition is associated with infective endocarditis or cerebral arterio-sclerosis, there is a group of cases in which the aneurysm is congenital, or depends on a congenital weakness in the arterial wall at certain points. To this congenital weakness of the arterial wall the case reported owes its interest.

CASE NOTES

History.—The patient, a married woman aged 33, was quite well until a month ago, when she had a slight attack of vomiting and complained of a vague headache. Since then she had not felt really well. On September 8th she fainted twice and vomited without warning. During the following week she complained of low occipital headache and pain in the back, and felt "feverish." On September 16th she walked to her doctor's house at 8 p.m. While in the surgery she suddenly collapsed and became comatose. The doctor applied artificial respiration and made arrangements for her admission to hospital.

Condition on Admission.—The patient was deeply comatose. The face and body were pale and cold. The muscles were flaccid and all reflexes absent. The pupils were widely dilated. Examination of the discs showed nothing abnormal. The systolic blood pressure was 110, and the heart rate 70, irregular, but not fibrillating. The urine contained no sugar, but a trace of albumin. No incontinence. Lumbar puncture obtained blood.

Progress.—Artificial respiration was maintained until 2.30 a.m., when intratracheal air was given. Fibrillation was noted at 3 a.m. Death occurred at 3.30 a.m.

Necropsy.—A complete post-mortem examination was made with the following findings. The convolutions of the cerebrum were flattened, and there was a large amount of blood clot in the pia-arachnoid at the base of the brain. The haemorrhage extended along the sulci over the right side of the cerebrum. The fourth ventricle contained blood clot, the lateral ventricles blood-stained cerebro-spinal fluid. Over the junction of the right anterior cerebral and anterior communicating artery was a pale fibrinous clot, about the size of a pea, evidently the remains of an older haemorrhage. The two frontal lobes were adherent to each other in this area. On lifting off this clot there was found a saccular aneurysm measuring 1 by 0.5 by 0.5 cm. occupying the space between the two anterior cerebrals and springing from the junction of the above arteries. The aneurysm showed a white fibrous-looking wall, thinned on the lower side, where it was ruptured. The other blood vessels of the brain showed no abnormality. The pericardium was adherent to the posterior aspect of the left ventricle by some old cord-like adhesions over an area of 2 cm. square. No other abnormality was found in the body. Microscopical examination of the liver and kidneys revealed no sign of disease. The Wassermann reaction of the blood obtained at the post-mortem examination was negative.

COMMENTARY

On reviewing the case in the light of the necropsy, it is evident that the attack on September 8th was due to a leakage from the aneurysm causing a small subarachnoid haemorrhage, which became arrested before causing material damage to the brain or cranial nerves. The subsequent attack was due to a sudden large haemorrhage causing a rapid and fatal compression of the medulla. No evidence of the presence of an aneurysm was detectable before rupture.

The clinical symptoms of a congenital aneurysm may be conveniently divided into symptoms prior to rupture and those following rupture.

Before rupture, localizing symptoms causing pressure on neighbouring structures may be recognized. In the region of the anterior half of the circle of Willis the second, third, fourth, fifth, or sixth nerve may be irritated. Thus a case has been reported where an intractable and apparently idiopathic trigeminal neuralgia was the only symptom. Again, an irregularity of the pupil on one side might be the only tell-tale sign. In the posterior half of the circle of Willis, pressure on the brain stem, in addition to paralyses of the last four cranial nerves, might give rise to paraplegia, cerebellar symptoms, dysarthria, dysphagia, or contralateral hemianaesthesia.

After rupture, leakage of blood into the subarachnoid space at the base of the brain gives rise to clinical signs upon which a diagnosis may be made with reasonable certainty, although meningitis or influenza may be closely simulated. Depending upon the rate of the haemorrhage, the intensity of the symptoms varies. Loss of consciousness passes on to deep coma with a severe haemorrhage, while with a small one, giddiness, headache, and vomiting may be the only

effect. Moderate pyrexia, stiffness of the neck, and positive Kernig's sign may be present, so that except for the difference in the cerebro-spinal fluid or the suddenness of onset or a possible previous attack, a diagnosis of meningitis might well be made.

C. P. Symonds gives a full report on this type of haemorrhage, and points out that Sir William Gull in 1859 was the first to recognize its comparative frequency.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

LACTATION IN ACCESSORY BREASTS

While the occurrence of accessory breasts is not uncommon, a case in which they actively functioned may deserve recording.

I attended, in September last, the confinement of a primipara, aged 23. She had a normal pregnancy up to the third month, when she noticed for the first time a lump in the right axilla immediately behind the anterior fold. At the eighth month a similar lump appeared in the left axilla. These lumps presented no true nipples, but in each there was a small dilated pore in the middle of the overlying skin. On the right side, midway between the true nipple and the umbilicus, was a small elevated nipple without any appreciable breast tissue beneath it.

On the second day after delivery the axillary lumps swelled concurrently with the true breasts, and reached the size of small oranges. A considerable quantity of milk exuded from the central pore of each. There was no change in the right accessory nipple. The accessory breasts gave an insufficient supply of milk to be of use to the child, and caused inconvenience to the mother by reason of pain and wetting of the clothes. They decreased in size in the absence of the sucking stimulus, and there was an uneventful puerperium.

I have seen several other cases of accessory breasts, but it is so rare for lactation to occur in axillary breasts that I think this case is of much interest.

I am indebted to Dr. E. Robertson for permission to publish this short account of the case.

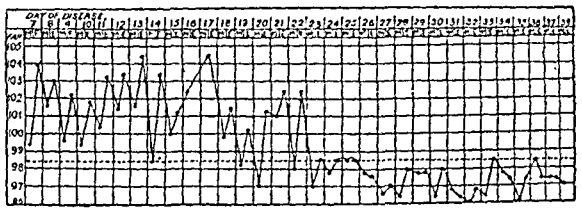
ARNOLD HINDHAUGH,
M.B., B.S., M.R.C.S.
London Hospital, E.1.

A CASE OF GLANDULAR FEVER

In view of the recent correspondence in the *Journal* on this subject, the following case may be of interest, especially in view of the fact that at no time during the illness was there any rash, a symptom which appears to have been a feature in some of the cases described by your correspondents.

J. M., aged 13, was taken ill on June 14th, 1930. When I first saw him he was listless and suffering from general malaise and a severe headache. He had a temperature of 103° F.; pulse 80. He gave a history of being on the river in a boat in strong sunshine, wearing only his school cap. After a short interval of three or four days, during which his temperature became normal, he again suffered from a rise of temperature, and complained of sore throat, pain in the neck, and general malaise.

On examination the throat was slightly red, tongue furred and dry, chest organs normal, but the spleen was distinctly palpable. The cervical lymph glands were enlarged on both sides, and the glands in both the carotid and posterior triangles were involved. Further search revealed slight enlargement of the lymph glands in the axillae. As the illness progressed the cervical glands became larger, very swollen and tender, and extremely painful. This persisted throughout the disease, during which there was considerable pyrexia. I enclose the temperature chart, from which it will be seen that the range was from 97° to over 104°. After a preliminary diagnosis of heat stroke, which had hurriedly to be revised, I came to the conclusion that I was dealing with a case of glandular fever, and this diagnosis was borne



out by the blood count, the details of which are as follows: red blood cells, 6,000,000 per c.mm.; haemoglobin, 80 per cent.; colour index, 0.7. White blood cells, 18,000 per c.mm. Differential white cell count: polymorphs, 9,180 (51 per cent).; lymphocytes, 8,640 (48 per cent.); large mononuclears, 180 (1 per cent.); eosinophils, *nil*.

After lasting for twenty-two days, the temperature fell by crisis, and the glands gradually began to recede in size. Recovery has been uneventful, except that the convalescence has been slow, and the boy has even now not yet regained his usual spirits. There was never at any time any suspicion of a rash.

In my view the chief points of interest in this case are: (1) the blood count, which revealed a moderate degree of leucocytosis, but mainly of the small lymphocytes, whereas some of your correspondents found that the increase was in the large lymphocytes; (2) the absence of rash.

I am indebted to Dr. W. H. McKinstry, pathologist to the Willesden General Hospital, who kindly did the blood count, and to Dr. C. R. Box, F.R.C.P., physician to the London Fever Hospital, who came at my request and confirmed the diagnosis.

London, N.W.2. E. C. WHITEHALL COOKE.

Reports of Societies

THE TREATMENT OF PNEUMONIA

At the meeting of the Medical Society of London on March 10th, with Dr. R. A. YOUNG in the chair, a discussion took place on the treatment of pneumonia.

Lord DAWSON OF PENN said that the treatment of lobar pneumonia had for centuries caused concern and controversy, justified by the prevalence and high mortality of the disease, and by the way in which it attacked both the robust and the unhealthy. One out of every 1,300 of the population succumbed to it every year. The attitude of mind towards the treatment of pneumonia changed from the time when it was established as an infection by a pneumococcus usually localized in the lung and pleura. He believed that specific therapy gave the greatest hope. The development of the serum treatment of pneumonia had followed the classification of the pneumococcus by Cole and other workers into four etiological groups. Of these the first, second, and third were specific types, while the fourth was a motley collection of serological strains. The serum contained protective substances similar to those which the patient's body was trying to produce, and did in fact produce, at the crisis in large amount if prognosis was favourable. These substances were antibacterial, not antitoxic. Their efficacy was commonly tested by their ability to protect mice from death when injected simultaneously with a lethal dose of organisms. Groups 1 and 2 accounted for 50 to 75 per cent. of the total cases. If, therefore, something could be done for these two groups, material progress would be made. Yet, in practice, serum treatment had not made much headway; probably

the explanation lay in the inevitable delay in deciding as to type. In acute disease, serum must be administered early. The bulk of the injections and the frequency with which they had to be given in the early stages was a serious handicap. It was a big proposition to have to give 100 c.cm. intravenously every eight hours for the first two days. These objections had in large measure been removed, however, by the introduction of Felton's serum, which was polyvalent to Groups 1 and 2, was in a concentrated and refined form, and in the making of which a considerable number of the chances of anaphylaxis were eliminated. Without "typing" the doctor could give the serum at the moment he made the diagnosis of pneumonia, for the chances were that the group would be 1 or 2, and if it were 3 or 4 no harm would be done. The fact that it was immediately possible to give a serum in a disease so severe and so brief in its course was a great gain. Tests for hypersensitiveness had to be made; one was that of putting two drops of undiluted horse serum into the conjunctiva, another was the intradermal injection of a 10 per cent. solution in normal saline. The results of this serum treatment were encouraging, though it was too early to say that they were conclusive. Lord Dawson referred to two recent reports, from the Royal Infirmaries of Edinburgh and Glasgow, dealing respectively with 89 and 57 cases, but sufficient for the formation of impressions. There was ground for thinking that, besides reducing the mortality, the prompt use of polyvalent serum, at any rate as regards Type I, cut short the attack, the day of the crisis being brought nearer to the sixth. Further, in Edinburgh the feeling was that the severity of the disease was less. The time had come for the more widespread employment of Felton's serum, used promptly as soon as pneumonia was diagnosed, with doses given intravenously, after rapid tests for hypersensitization, every eight hours during the first twenty-four, and subsequently twice or three times in the twenty-four hours, according to the temperature, pulse, and condition of the patient. Everything was to be gained by being bold in the early stages.

Turning to the problems of the treatment of pneumonia outside the acquirement of immunity, Lord Dawson said that anoxaemia showed itself in blueness of the lips and nails, and it had been suggested that the blocking of the alveoli with exudate must cut down oxygen intake and the output of CO_2 and waste products. But was that an adequate explanation? Cases could be recalled, ominously stricken from the commencement, in which cyanosis and blueness were prominent, yet there had been no time for consolidation in the lung. What happened was that the pneumococci damaged the alveolar epithelium and deprived it of its functional efficiency. In this way anoxaemia would be linked with toxaemia, which was known to exist clinically. This association explained why the alleviation of symptoms by oxygen was sometimes partial and transient. Oxygen administration was a supportive rather than a curative measure. It improved the appearance of the patient, and caused diminution of pulse rate, restlessness, and delirium, but it was transient; its chief value was that it enabled the patient to "hang on" in the hope that immunity might be reached. He discussed the methods of oxygen administration. The mask was of little use because it distressed the patient, who felt himself encompassed. In Chicago he had seen a small two-bed oxygen ward, in which any quantity of oxygen desired could be produced, with adequate ventilation and means of regulating temperature and humidity. An oxygen concentration of 60 per cent. was not good for the attendants, and was unnecessary for the patient; about 40 per cent. was nearly always adequate. Portable oxygen tents were employed in many places; they were like small sedan chairs, with windows on every side; these prevented the patient from feeling himself encompassed, and a saturation of 40 or 50 per cent. could be secured. With regard to oxygen catheters, if one of the calibrated reducing valves was used, the supply of oxygen could be regulated easily, 2 litres per minute being delivered through the catheter, giving a richness of oxygen equal to 30 per cent.

Discussing alleviative measures, Lord Dawson said that opium, its alkaloids and allies, were beyond value. Some patients, who were fully conscious, endured anguish of thought as well as bodily stress and pain. If that load could be lightened it was great gain—and what was better in many instances than morphine? The hesitancy to use morphine or its allies—for example, heroin—was not justified. The only condition under which morphine might require to be withheld or used with great restraint was a generalized bronchitis, with an exudate blocking the tubes. When a patient was merely restless and sleepless a hypnotic was better than morphine. A little nepenthe might be given to ease the cough, and the hypnotic allowed to do the rest. Bromide and chloral were valuable sedatives, and occasionally it was found that some of the synthetic hypnotics reduced an uncomfortable blueness in certain patients. Alcohol had the advantage of being a food that did not require digestion, and therefore saved the administration of other forms of nourishment. Moreover, it lightened worries and assisted sleep. It was often a mistake to order brandy, for how many people in these days could afford brandy that was worth taking? On the other hand, good whisky could be obtained for a relatively small price. It was seldom wise to press alcohol on those who disliked it.

Professor W. H. WYNN confined himself to the discussion of vaccine treatment. It was unfortunate that the early work with vaccines was on subjects of chronic infection who were sensitized and reacted easily. It was assumed that these phenomena, found in chronic infections, were present in all states of infection, hence the fear of using vaccines in acute infections such as pneumonia. In acute infections specific antibodies were present only after a certain interval, as their formation was comparatively slow. Until the antibodies were produced the patient was unsensitized, and there was an interval before sensitization occurred, which afforded the opportunity of intervening safely with an adequate amount of vaccine. These antibodies were strictly specific, and if they only were to be depended upon it would be impossible to get a rapid result. But fortunately the vaccine had an immediate action in producing non-specific antibodies. Early work on vaccines was concerned almost entirely with the production of specific antibodies, but it was frequently observed that immediate improvement occurred after the single injection of the vaccine, a fact impossible to explain by any of the then understood theories of immunity. Wright and others had shown that the adding of a vaccine to blood produced a mobilization of non-specific antibodies, and the blood became bactericidal. It was this non-specific form of immunity which was illustrated in the early treatment of acute infections. It was probable that any given vaccine would cause a similar effect, because this was a non-specific action, which affected other microbes besides those contained in the actual vaccine. The object of vaccine treatment in pneumonia was to produce a real immunity while the curve of toxaemia was rising. In this early stage the circulation through the lung was unimpeded, and the antibodies in the blood were able to obtain access to the organisms. In pneumonia there was thus an interval during which the patient was unsensitized, and in which prompt action might control or abort the infection. He urged the importance, therefore, of early treatment. The result in any case of pneumonia probably

depended upon the happenings of the first forty-eight hours. The vaccine was a straightforward emulsion of the organisms, sterilized by heat, and produced from primary growth as far as possible under twenty-four hours old. At first, for lobar pneumonia, he had used a vaccine containing only the pneumococcus, and for influenzal broncho-pneumonia a vaccine containing equal numbers of pneumococcic, streptococcic, and influenzal strains, but in recent years he had used the mixed vaccine for all cases. For the adult the minimum dose was 100 million, but even twice or three times that was often given, and for children the doses were proportionately smaller, though he was approximating the child to the adult dose. If the vaccine was injected within the first twenty-four hours the temperature would fall during the next twenty-four to forty-eight hours, and this rapid fall was one of the most striking things he had seen in the whole range of therapeutics. On the second or third day it was, of course, harder to overtake the infection. In a hundred consecutive cases of lobar pneumonia, all severe, forty-nine patients were injected during the first three days, and of these only one died.

Dr. R. A. O'BRIEN confessed that he was still far from convinced of the efficacy of antipneumococcus serum. He said this unwillingly, because for twenty years his job had been serology, and if serum did not prove to be one of those things which had come to stay it would be a great disappointment to him. But he must hold that only those things had come to stay the utility of which could be proved in the laboratory with laboratory animals. He then went on to examine the evidence afforded from the Rockefeller Institute relating to the use of serum in pneumonia, and after passing in review the work of Avery, Park, Rosenbluth, and others, he said that Type I was the only type in which the figures even of the Americans themselves showed a definitely favourable result, obtained in a long series of cases. On the question of dosage and units Dr. O'Brien said he found great difficulty in understanding the American work, and for the moment he did not see, from the point of view of laboratory experiment, how it was possible to get any further in this matter in England; he was very despondent about it. The clinical testimony made one feel that, given a case of Type I or Type II infection, serum ought to be used, because it might tip the balance, and yet on the laboratory side he felt that justification was lacking. Even to-day in New York the note was not one of complete conviction, though Park had told him that he was as convinced of the utility of Type I serum as of diphtheria antibody. But the laboratory control of treatment was going to be a very troublesome matter, and he was doubtful whether in England the method would pass the sceptical statistician.

Dr. NATHAN RAW said that some years ago he had carried out a prolonged observation of vaccine therapy, using the Burroughs Wellcome stock pneumococcic vaccine. He treated 250 consecutive cases with this preparation, and in some the effects were theatrical, but on the whole the death rate was lowered only by some 3 per cent. As the vaccine was a stock one it was, more or less, a shot in the dark, but he felt convinced that if a specific vaccine from the pneumococcus were available the results would be extremely good. A recent paper by Park stated that there were thirty distinct types of pneumococci. The difficulty up to now had been that it had not been possible to obtain for the vaccine treatment of pneumonia the exact type of pneumococcus causing the disease.

Dr. R. S JOHNSON described some work on serum treatment on which he, with Dr. Armstrong, had been engaged for the last five months. The investigation was begun at St. Bartholomew's, though it later extended to other hospitals, on Types I and II cases, with the serum prepared by Felton. The results (which, when the work was completed, would be published in full) had shown the great value of serum. An additional help had been a method of determining the pneumococcal type before serum treatment was begun; this was a rapid method of typing by exposition of the peritoneum of the living mouse and the microscopical agglutination test. Of fifteen cases of Type I treated, eight were early cases (first three days), and all showed a striking improvement; of the seven late cases, four were markedly improved, two improved, and one uninfluenced. Of eight cases of Type II treated, four were early cases, and three of these patients improved dramatically; the other, after an initial improvement, had a relapse and died of oedema of the lung; of the four late cases, two were greatly improved and two showed no benefit. The aim of dosage was to give initially 20,000 protective units of the homologous type antibody. Dr. R. ARMSTRONG added a few words on the same series of observations. He asked whether one was justified in regarding only mortality experience and statistics in connexion with pneumonia. There was an infinite variety of conditions which prejudiced the course of pneumonia by itself, and might lead to the death of the patient irrespective of his pneumonic condition. What impressed one in this new treatment was the striking improvement in the patient's general condition. He believed, with Park, that the serum had come to stay, and he thought that the method of rapid typing would revolutionize the treatment.

Dr. WALTER BROADBENT mentioned that he used an Italian serum in 1910, which was very effective until about 1916, when it became completely useless, presumably because the type of pneumonia had changed. A serum made at the Pasteur Institute was very effective in England up to about 1923, when it also failed completely. Dr. EAST showed graphs of a small series of cases treated with the Lister Institute serum, from which he thought some advantage had been gained. Dr. C. B. HEALD asked for any experiences of the use of diathermy in the treatment of pneumonia. Professor WYNN said that his experience in Birmingham was that the majority of pneumonias were not purely of the pneumococcal type; a very large number were influenzal pneumonias in which the streptococcus was the important organism, so that serum had not much application towards those. With regard to alcohol, he related an observation in which on one side of the ward practically every patient had alcohol, and on the other side no patient had alcohol. Among those who had alcohol the mortality was 68 per cent., among those who took none it was 21 per cent.

Lord DAWSON, in reply, said, with regard to alcohol, that he could not conceive of any remedy in pneumonia being used as a routine unless it were something which claimed to be a specific treatment. To use alcohol in every case would be an act of folly. All endeavours to reduce remedies and the testing of their virtues to the level of statistics did not lend themselves effectively to treatment. When they got to logarithms, he wondered whether they were not getting far away from the actualities of their work. He appreciated the scepticism of the laboratory, but he hoped the clinician would not be discouraged by it. Greatly as he admired American methods, he always came back to this country feeling that here was a "clinical wisdom which is not excelled in any other country in the world." With regard to serum therapy, his attitude was one of chastened optimism, and he believed it was worth while going forward with this investigation. He thought that too much stress had been laid on the value of autogenous vaccines in acute infections. He thought the balance was in favour of an efficient standardized vaccine with a good antigen content.

FRACTURED BASE: EFFECTS ON HEARING

At a meeting of the Section of Otology of the Royal Society of Medicine on March 6th, with Mr. ALEXANDER TWEEDIE in the chair, a discussion took place on the effects on hearing following fractured base of the skull.

Mr. E. D. D. DAVIS, in an opening paper, after a reference to the increased frequency of such injuries, due largely to motor and especially motor cycle accidents, said that the extent of the injury varied considerably with the degree of violence and the exact situation at which the blow was received. The capsule of the internal ear or labyrinth was rarely found fractured except in fatal cases; among the patients who survived it was the middle ear which was practically always damaged. The auditory meatus was often involved in the fracture, which appeared to split the meatus longitudinally, dividing it into an upper and a lower half. A moderate blow on the temporal fossa might produce a radiating fracture which cracked the roof of the middle ear without rupturing the drum. He had observed four such cases, and the only outward indication was deafness. More commonly the upper half of the drum was ruptured and the blood escaped through the auditory meatus, and also into the nasal and pharyngeal passages. It was significant that in a number of recorded cases where the internal ear had been fractured cerebro-spinal fluid had been present in the discharge. Haemorrhage from both ears was always an unfavourable sign, and the mortality was 66 per cent., whereas when there was haemorrhage from one ear only, the mortality was 39 per cent. The average mortality for all cases of fractured skull was 40 per cent. Where a middle-ear suppuration had existed before the injury the probability of meningeal infection was very great, and the prognosis correspondingly unfavourable. In some cases the injury to the ear was followed by an open suppuration, which materially added to the damage. Mastoid suppuration has also been known to follow a fracture, and such a complication was likely to lead to meningeal infection. Some of these cases of local suppuration, when seen late, could not be distinguished from the ordinary chronic middle-ear suppuration occurring without injury; hence the necessity of examining these patients as soon after injury as possible. The degree of deafness arising from fractures of the skull naturally varied considerably with the extent of the damage. There were roughly three grades of injury to the ear: (1) haemorrhage into the middle ear only, without rupture of the drum, possibly due to a crack in the roof of the middle ear, and detected by the typical bluish appearance of the drum; (2) rupture of the drum and comminution of the roof of the tympanum and meatus; (3) severe fractures in which the capsule of the internal ear had been fractured. Patients in whom fracture was followed by local suppuration suffered most loss of hearing, and the deafness often became permanent. Any improvement in hearing usually became manifest eight weeks after the injury, and if deafness remained after that period it was likely to be permanent. Tinnitus occurred in some of the severe injuries, and also in injuries, not severe, to highly strung patients. The response to treatment of these cases of tinnitus was slow and indifferent. The lesion was not always of the internal ear; most cases of tinnitus showed deafness of the middle-ear type and excitability of labyrinth, and no other abnormality. It was possible that the tinnitus was of central origin, and due to injury of the brain or central nervous mechanism. As to the treatment of the ears following head injuries, a careful watch should be maintained for the onset of suppuration. Absolute rest in bed over a long period was essential, and the less done to the ear the better. As soon as there was recovery from the original shock, the head should be raised by means of pillows, and the auditory meatus gently cleansed with spirit. If there was any discharge of cerebro-spinal fluid the skin should be dried and smeared with an antiseptic ointment, for cerebro-spinal fluid caused a good deal of skin irritation. Packing the meatus with gauze, and, of course, syringing and drops, were to be deprecated. One had always to consider intracranial haemorrhage, for which there should be a free escape. If suppuration occurred, vigorous methods should be adopted to establish free drainage. The tympanic membrane should be incised if necessary, and there should be no hesitation in performing a simple mastoid operation. The early recognition and treatment of suppuration was essential for the prevention of dangerous meningeal or intracranial infection.

The PRESIDENT said that the otologist, notwithstanding requests which he made to his colleagues, did not see cases of concussion sufficiently early; they were referred for deafness weeks or months after the injury. It was curious to note how there might be a good recovery of hearing after a complete filling of the tympanum, with distension of the membrane. He narrated a recent case of a young man who sustained injury while playing Rugby football, being unconscious for twenty minutes. He insisted, however, on going to a dance the next day, and to a boxing contest later, and the following week he again played football, and was knocked out. Some bleeding was then noticed from his ear, and a regular slit was discovered in the membrane, the well-known blue-black distension being observable. The young man, however, scoffed at the idea of a few days' rest in bed, and, so far as the speaker knew, undertook no treatment, and got better!

Dr. DAN MCKENZIE said that fracture of the skull was one of the commonest lesions found in motor accidents, and he thought that surgeons should be encouraged to call in the aid of the otologist with regard to both diagnosis and treatment. Obviously a fracture which went through the middle ear, and possibly up the membrane, was in a sense a compound fracture. A large number of the patients died from meningitis, sometimes months after the accident, due to infection through the meatus and internal ear, as a result of fracture of the temporal bone. In such cases the right thing to do was to operate very early indeed in order to prevent extension to the meninges. Apart from this, the cases called for a "masterly inactivity," lest the very danger it was desired to obviate should be incurred.

Mr. L. GRAHAM BROWN agreed with Mr. Davis that the best method of treating the meatus was by means of spirit, and if suppuration occurred more drastic methods of cleaning must be adopted. He believed that drainage was essential, because in these cases a fatal ending was due to meningitis. In cases coming up for an opinion with a view to compensation there was very often the complication of suppurative otitis media, and it was difficult to say whether the accident caused the otitis media or whether that was a pre-existing condition. To get any decided opinion the case must be seen early.

Mr. HAROLD KISCH spoke of the value of x-ray examination in the diagnosis of difficult cases. The otologist was usually requested to give an opinion on three points: whether the bleeding from the ear was due to a fractured base, whether deafness was likely to be permanent, and what was the prognosis as regards life. Occasionally bleeding from the ear might be due to an injury to the external auditory meatus alone. He wondered why Mr. Davis had described the cerebro-spinal fluid as having an irritating effect on the skin. What constituent in the fluid caused irritation?

Mr. F. W. WATKYN-THOMAS suggested that the development of late meningitis was explained by the fact that the labyrinth, when fractured, in a large number of cases did not heal by bone but by scar tissue. Therefore they

depended upon the happenings of the first forty-eight hours. The vaccine was a straightforward emulsion of the organisms, sterilized by heat, and produced from primary growth as far as possible under twenty-four hours old. At first, for lobar pneumonia, he had used a vaccine containing only the pneumococcus, and for influenzal broncho-pneumonia a vaccine containing equal numbers of pneumococcic, streptococcic, and influenzal strains, but in recent years he had used the mixed vaccine for all cases. For the adult the minimum dose was 100 million, but even twice or three times that was often given, and for children the doses were proportionately smaller, though he was approximating the child to the adult dose. If the vaccine was injected within the first twenty-four hours the temperature would fall during the next twenty-four to forty-eight hours, and this rapid fall was one of the most striking things he had seen in the whole range of therapeutics. On the second or third day it was, of course, harder to overtake the infection. In a hundred consecutive cases of lobar pneumonia, all severe, forty-nine patients were injected during the first three days, and of these only one died.

Dr. R. A. O'BRIEN confessed that he was still far from convinced of the efficacy of antipneumococcus serum. He said this unwillingly, because for twenty years his job had been serology, and if serum did not prove to be one of those things which had come to stay it would be a great disappointment to him. But he must hold that only those things had come to stay the utility of which could be proved in the laboratory with laboratory animals. He then went on to examine the evidence afforded from the Rockefeller Institute relating to the use of serum in pneumonia, and after passing in review the work of Avery, Park, Rosenbluth, and others, he said that Type I was the only type in which the figures even of the Americans themselves showed a definitely favourable result, obtained in a long series of cases. On the question of dosage and units Dr. O'Brien said he found great difficulty in understanding the American work, and for the moment he did not see, from the point of view of laboratory experiment, how it was possible to get any further in this matter in England; he was very despondent about it. The clinical testimony made one feel that, given a case of Type I or Type II infection, serum ought to be used, because it might tip the balance, and yet on the laboratory side he felt that justification was lacking. Even to-day in New York the note was not one of complete conviction, though Park had told him that he was as convinced of the utility of Type I serum as of diphtheria antibody. But the laboratory control of treatment was going to be a very troublesome matter, and he was doubtful whether in England the method would pass the sceptical statistician.

Dr. NATHAN RAW said that some years ago he had carried out a prolonged observation of vaccine therapy, using the Burroughs Wellcome stock pneumococcic vaccine. He treated 250 consecutive cases with this preparation, and in some the effects were theatrical, but on the whole the death rate was lowered only by some 3 per cent. As the vaccine was a stock one it was, more or less, a shot in the dark, but he felt convinced that if a specific vaccine from the pneumococcus were available the results would be extremely good. A recent paper by Park stated that there were thirty distinct types of pneumococci. The difficulty up to now had been that it had not been possible to obtain for the vaccine treatment of pneumonia the exact type of pneumococcus causing the disease.

Dr. R. S. JOHNSON described some work on serum treatment on which he, with Dr. Armstrong, had been engaged for the last five months. The investigation was begun at St. Bartholomew's, though it later extended to other hospitals, on Types I and II cases, with the serum prepared by Felton. The results (which, when the work was completed, would be published in full) had shown the great value of serum. With regard to serum therapy, his attitude was one of chastened optimism, and he believed it was worth while going forward with this investigation. He thought that too much stress had been laid on the value of autogenous vaccines in acute infections. He thought the balance was in favour of an efficient standardized vaccine with a good antigen content.

FRACTURED BASE: EFFECTS ON HEARING

At a meeting of the Section of Otology of the Royal Society of Medicine on March 6th, with Mr. ALEXANDER TWEEDIE in the chair, a discussion took place on the effects on hearing following fractured base of the skull.

Mr. E. D. D. DAVIS, in an opening paper, after a reference to the increased frequency of such injuries, due largely to motor and especially motor cycle accidents, said that the extent of the injury varied considerably with the degree of violence and the exact situation at which the blow was received. The capsule of the internal ear or labyrinth was rarely found fractured except in fatal cases; among the patients who survived it was the middle ear which was practically always damaged. The auditory meatus was often involved in the fracture, which appeared to split the meatus longitudinally, dividing it into an upper and a lower half. A moderate blow on the temporal fossa might produce a radiating fracture which cracked the roof of the middle ear without rupturing the drum. He had observed four such cases, and the only outward indication was deafness. More commonly the upper half of the drum was ruptured and the blood escaped through the auditory meatus, and also into the nasal and pharyngeal passages. It was significant that in a number of recorded cases where the internal ear had been fractured cerebro-spinal fluid had been present in the discharge. Haemorrhage from both ears was always an unfavourable sign, and the mortality was 66 per cent., whereas when there was haemorrhage from one ear only, the mortality was 39 per cent. The average mortality for all cases of fractured skull was 40 per cent. Where a middle-ear suppuration had existed before the injury the probability of meningeal infection was very great, and the prognosis correspondingly unfavourable. In some cases the injury to the ear was followed by an open suppuration, which materially added to the damage. Mastoid suppuration has also been known to follow a fracture, and such a complication was likely to lead to meningeal infection. Some of these cases of local suppuration, when seen late, could not be distinguished from the ordinary chronic middle-ear suppuration occurring without injury; hence the necessity of examining these patients as soon after injury as possible. The degree of deafness arising from fractures of the skull naturally varied considerably with the extent of the damage. There were roughly three grades of injury to the ear: (1) haemorrhage into the middle ear only, without rupture of the drum, possibly due to a crack in the roof of the middle ear, and detected by the typical bluish appearance of the drum; (2) rupture of the drum and comminution of the roof of the tympanum and meatus; (3) severe fractures in which the capsule of the internal ear had been fractured. Patients in whom fracture was followed by local suppuration suffered most loss of hearing, and the deafness often became permanent. Any improvement in hearing usually became manifest eight weeks after the injury, and if deafness remained after that period it was likely to be permanent. Tinnitus occurred in some of the severe injuries, and also in injuries, not severe, to highly strung patients. The response to treatment of these cases of tinnitus was slow and indifferent. The lesion was not always of the internal ear; most cases of tinnitus showed deafness of the middle-ear type and excitability of labyrinth, and no other abnormality. It was possible that the tinnitus was of central origin, and due to injury of the brain or central nervous mechanism. As to the treatment of the ears following head injuries, a careful watch should be maintained for the onset of suppuration. Absolute rest in bed over a long period was essential, and the less done to the ear the better. As soon as there was recovery from the original shock, the head should be raised by means of pillows, and the auditory meatus gently cleansed with spirit. If there was any discharge of cerebro-spinal fluid the skin should be dried and smeared with an antiseptic ointment, for cerebro-spinal fluid caused a good deal of skin irritation. Packing the meatus with gauze, and, of course, syringing and drops, were to be deprecated. One had always to consider intracranial haemorrhage, for which there should be a free escape. If suppuration occurred, vigorous methods should be adopted to establish free drainage. The tympanic membrane should be incised if necessary, and there should be no hesitation in performing a simple mastoid operation. The early recognition and treatment of suppuration was essential for the prevention of dangerous meningeal or intracranial infection.

The PRESIDENT said that the otologist, notwithstanding requests which he made to his colleagues, did not see cases of concussion sufficiently early; they were referred for deafness weeks or months after the injury. It was curious to note how there might be a good recovery of hearing after a complete filling of the tympanum, with distension of the membrane. He narrated a recent case of a young man who sustained injury while playing Rugby football, being unconscious for twenty minutes. He insisted, however, on going to a dance the next day, and to a boxing contest later, and the following week he again played football, and was knocked out. Some bleeding was then noticed from his ear, and a regular slit was discovered in the membrane, the well-known blue-black distension being observable. The young man, however, scoffed at the idea of a few days' rest in bed, and, so far as the speaker knew, undertook no treatment, and got better!

Dr. DAN MCKENZIE said that fracture of the skull was one of the commonest lesions found in motor accidents, and he thought that surgeons should be encouraged to call in the aid of the otologist with regard to both diagnosis and treatment. Obviously a fracture which went through the middle ear, and possibly up the membrane, was in a sense a compound fracture. A large number of the patients died from meningitis, sometimes months after the accident, due to infection through the meatus and internal ear, as a result of fracture of the temporal bone. In such cases the right thing to do was to operate very early indeed in order to prevent extension to the meninges. Apart from this, the cases called for a "masterly inactivity," lest the very danger it was desired to obviate should be incurred.

Mr. L. GRAHAM BROWN agreed with Mr. Davis that the best method of treating the meatus was by means of spirit, and if suppuration occurred more drastic methods of cleaning must be adopted. He believed that drainage was essential, because in these cases a fatal ending was due to meningitis. In cases coming up for an opinion with a view to compensation there was very often the complication of suppurative otitis media, and it was difficult to say whether the accident caused the otitis media or whether that was a pre-existing condition. To get any decided opinion the case must be seen early.

Mr. HAROLD KISCH spoke of the value of *x*-ray examination in the diagnosis of difficult cases. The otologist was usually requested to give an opinion on three points: whether the bleeding from the ear was due to a fractured base, whether deafness was likely to be permanent, and what was the prognosis as regards life. Occasionally bleeding from the ear might be due to an injury to the external auditory meatus alone. He wondered why Mr. Davis had described the cerebro-spinal fluid as having an irritating effect on the skin. What constituent in the fluid caused irritation?

Mr. F. W. WATKYN-THOMAS suggested that the development of late meningitis was explained by the fact that the labyrinth, when fractured, in a large number of cases did not heal by bone but by scar tissue. Therefore any

succeeding infection of the ear was apt to set up a meningitis through an ill-guarded labyrinth. Mr. C. HAMBLEN THOMAS raised the question of the positive inferences to be drawn from the *x*-ray picture. Mr. HERBERT TILLEY thought that the cerebro-spinal fluid did have an irritative action on a sensitive skin. With regard to the treatment of fractured skulls associated with deafness and distended drums, he agreed that the less that was done the better. One important point to be borne in mind was that, apart from the condition of the ear, there might be concussion of the brain at the same time. Mr. J. F. O'MALLEY considered that the escape of cerebro-spinal fluid was not sufficient alone to give a bad prognosis; it was the underlying lesion that was of real importance. He gave an instance of a patient who lost an extraordinary amount of cerebro-spinal fluid, and apparently it had not affected his health in the least. Sir JAMES DUNDAS-GRANT said that the condition of the Eustachian tube afforded some indication as to the origin of the bleeding or suppuration. A narrow tube suggested that the suppuration was of old standing; if wide, it might be assumed that it was due to damage to the ear itself, and not to an old suppurative disease. Tinnitus or vertigo was often as much due to concussion as to the local damage to the ears. Mr. N. S. CARRUTHERS said that most of those who saw a patient with profuse sanious discharge from the ear after an accident were too apt to conclude that it was cerebro-spinal fluid. He had found sanious discharges coming from the ear which, on test, proved not to be cerebro-spinal fluid. Further experiences of particular cases were described by Mr. LIONEL COLLEDGE, Mr. BROUGHTON BARNES, and others.

Mr. DAVIS, in reply, said that he had had a number of cases radiographed, but in only one could he be reasonably sure from the *x*-ray result that there was a fracture. The objection to moving these patients to the *x*-ray room had to be considered, and the lack of positiveness in the *x*-ray findings was disappointing. With regard to cerebro-spinal fluid, he had noticed a skin irritation in two cases, but the point had also been emphasized in literature that the skin became sodden and there was a tendency to infection. The escape of the cerebro-spinal fluid appeared to indicate a serious lesion. There were cases which recovered after a profuse discharge, but he still maintained that the prognosis was bad. Some held the view, however, that a free discharge of cerebro-spinal fluid washed away any infection from the wound.

TREATMENT OF TOXIC GOITRE

At the February meeting of the Manchester Medical Society, with the president, Mr. J. HOWSON RAY, in the chair, a discussion took place on the treatment of toxic goitre.

Dr. J. CRIGHTON BRAMWELL briefly reviewed the principal therapeutic measures which had been employed in the past in the treatment of toxic goitre. He discussed the relative merits of surgical and non-surgical methods of treatment in primary and secondary Graves's disease. He concluded that at the present time surgical treatment was the method of choice in the more advanced cases, but expressed the opinion that, in the future, earlier diagnosis would render most cases of primary Graves's disease curable without surgical intervention.

Mr. JOHN MORLEY based his remarks on a series of 120 cases of primary exophthalmic goitre and 72 cases of toxic adenoma upon which he had operated. The mortality in the former group was 5 per cent., and in the latter 6.9 per cent. The tendency in and around Manchester to refer only the more severe cases to the surgeon inevitably involved a somewhat higher mortality than was found in surgical centres, where all cases, including the mildest, were treated by operation. The cause of death in most cases was myocardial weakness. The end-results of operation had been assessed by a questionary as to increase in weight since operation, continuance of palpitation, and ability to resume normal work. This was supplemented by personal interview when possible. The results of this investigation were tabulated as follows:

	Very Good	Good	Moderate	Poor
Primary exophthalmic goitre (97 cases)	60	24	6	7
Toxic adenoma (54 cases) ...	38	13	2	1

While there was general agreement that all cases of toxic adenoma or secondary toxic goitre should be operated on without undue delay, there was still much difference of opinion with regard to the indications for *x*-ray treatment or operation in primary exophthalmic goitre. Mr. Morley believed that *x*-ray treatment gave the best results in the less severe cases with small goitres. In such cases he favoured a course of *x*-ray treatment lasting three months, rigidly controlled by the effect on weight, pulse rate, and basal metabolic rate. If at the end of this test period there was no really striking improvement, he considered it wiser to advise operation at once in order to relieve the strain on the heart muscle. He drew attention to the fact that one-third of his cases of primary exophthalmic goitre had been treated without success by *x* rays before they came to operation. One patient who had undergone intensive *x*-ray treatment developed tetany after operation, but it was found, on going into her history again, that she had noticed similar attacks of tetany for four months before operation. This suggested that the *x*-ray treatment had damaged the parathyroids in her case. The effect of iodine medication was usually transient, and the early favourable effect of iodine on the pulse rate could not be repeated in many cases. He pleaded that iodine should be reserved as a powerful safeguard for the patient in the fortnight or so before operation. A sufficiently long period of pre-operative rest, with the closest co-operation of the physician in the treatment of the heart by digitalis, contributed largely to the safety of operation. Although general anaesthesia by gas and oxygen was safe in an average case, Mr. Morley expressed a growing preference for local anaesthesia in the more severe types and regarded it as especially necessary in those with auricular fibrillation. While operation was not the last word in the treatment of exophthalmic goitre, in the present state of our knowledge it must be regarded as the most rapid and most efficient form of treatment available.

Dr. E. O. GRAY reviewed in detail the results of medium voltage *x*-ray therapy in ninety-nine cases of toxic goitre treated at the Manchester Royal Infirmary during 1928. In his opinion, *x*-ray therapy was a valuable form of treatment in cases of exophthalmic goitre without visceral complications, and a four months' trial was indicated, provided the patient was able to attend regularly and had reasonably comfortable home conditions. If careful records of the symptoms, pulse rate, and weight were kept, it was usually possible at the end of this period to decide whether *x*-ray treatment would be successful in a particular case. A perfect functional result was obtained in 50 per cent. of the cases of exophthalmic goitre in this series, and a further 33 per cent. were markedly improved. *X*-ray therapy had also something to offer in cases of toxic adenoma, as, with a longer course of treatment, good palliative results were frequently obtained. Until it was proved that patients suffering from this type of toxic goitre inevitably developed cardiovascular damage in the course of time, *x*-ray treatment could be recommended if operation was undesirable.

DIGESTIVE DISORDERS IN BREAST-FED INFANTS

At the February meeting of the Edinburgh Obstetrical Society, with Dr. H. S. DAVIDSON in the chair, Dr. CHARLES MCNEIL read a paper on some minor digestive disorders in breast-fed infants during the first month.

Dr. McNeil said that the difficulties attending breast-feeding were not often discussed, but they were not infrequent, and were especially common in the first month—a critical period for the digestive system of the infant. The following four clinical groups included most of the digestive troubles of the baby at this time: (1) mild diarrhoea with green stools; (2) a special type of vomiting; (3) a special type of constipation; (4) failure to gain weight. All the groups had certain common features. At the outset, all were trivial in their effect on health and digestion, but were apt to become chronic and more serious. They were commonly ascribed to some fault in the mother's milk and often led to weaning. A great many of them began about the end of the first week of life, at a time when the first free flow of maternal milk took place. The fourth large group of cases, where the symptom was a failure to gain weight, was produced by a variety of conditions in the mother or child, and demanded a careful examination of both, and weaning was very seldom indicated. The first group, with the symptom of green and frequent stools, was also a large one. The condition was very common, and at first not pathological. It often righted itself, but it was easily overlooked, and might drift into a condition of true chronic dyspepsia. It often appeared about the end of the first week. There was no evidence of dyspepsia at the outset, and it was due to increased peristaltic action of the bowel, associated with the free flow of milk. At first no treatment was required. If it continued simple measures such as a small dose of castor oil combined with a temporary reduction in breast-nursing, were usually sufficient. If these failed, the use of a plain petroleum emulsion, half a teaspoonful well diluted, twice daily, was recommended as an effective and simple remedy. The second group, that in which the symptom was vomiting, had special clinical features which distinguished it from other types of vomiting in the early weeks of life. This type also appeared usually at the end of the first week. Although the vomiting was frequent and explosive, the baby looked well and continued to gain weight for a time; there might or might not be air swallowing as well. It was much commoner in girls especially the nervous and impatient type. The condition was not easy to put right at once, but general measures directed to soothing the baby during and after suckling, and the giving of one or two grains of sodium citrate in a tablespoonful of warm water before nursing, always improved it, and even if vomiting did not stop, the baby continued to thrive. The condition was due to maladjustment of peristalsis and sphincter action in the stomach, or pyloric spasm, and was never an indication for weaning. It had, however, to be distinguished from pyloric stenosis, which might occur in girls, and from the very rare cases of true idiosyncrasy to maternal milk. The third group referred to a special type of constipation in breast-fed babies. The symptom might appear suddenly after a period of loose green motions; the stool was at first of normal consistence and colour, and in all other respects the baby was quite well. The condition here was one of anal spasm. In its treatment, aperient medicine or the usual anal suppositories were either useless or merely palliative, but anal dilatation with the finger, combined with the use of a simple ointment such as 2 per cent. ichthyol, rapidly cured the condition. These first three groups made up a large number of the minor digestive disorders of the breast-fed infant in the first month of life. They were due neither to a fault in the maternal milk nor to disorder of the chemical processes of digestion, but to some maladjustment in the mechanism of peristaltic action and sphincter control in the stomach and large bowel. This maladjustment was specially likely to happen at that time when the first free flow of milk took place—that is, about the end of the first week. Although at first trivial in their effect, these types of minor disorders were liable, if uncorrected, to lead to more serious chronic dyspepsia.

VAGINAL HYSTERECTOMY

At the last meeting of the North of England Obstetrical and Gynaecological Society, held in Manchester, Mr. W. W. KING (Sheffield) was installed as president for the ensuing year.

Dr. S. B. HERD (Liverpool), in a paper on vaginal hysterectomy, pointed out that little support for the operation was to be found in the textbooks, some being frankly antagonistic. There was also need of agreement as to the indications and technique. The present communication was based on a series of fifty cases. In the majority of these the vagina was prepared by hyperchlorite packs and douches for two days before operation. The cervix was closed by three or four silk sutures, which also acted as tractors. The utero-vesicle pouch and Douglas's pouch were opened in the usual way. Dr. Herd recommended early ligature and division of the utero-sacral ligaments to give greater mobility, after which it was easy to work up the sides and secure the uterine arteries. He had not found it necessary to bisect the uterus or remove fibroids piecemeal. The appendages could be removed with the uterus or dealt with separately where removal was advisable. All stumps were fixed to the vault, with their cut surfaces projecting into the vagina after partial closure of the peritoneal cavity. In cases of prolapse a vaginal repair was combined with hysterectomy. The contraindications given were carcinoma of the body or cervix, inflamed appendages, fixation of the body or uterine enlargement out of proportion to the vagina. Of the cases reported by Dr. Herd only six patients were under 40 years of age, the average age being 44, and the average stay in hospital after operation seventeen days. Four were cases of carcinoma; these did not do well. Or the remaining forty-six, forty-three made excellent recoveries. There was one death from broncho-pneumonia, one case of haemorrhage on the tenth day controlled by packing, and one case of pyelitis. The most noteworthy feature of the series of cases was the complete absence of shock and the rapidity with which recovery occurred.

The PRESIDENT, Mr. A. GOUGH, and Professor MILES PHILLIPS spoke strongly in favour of the method, Professor Phillips remarking that no one had the right to call himself a gynaecologist who did not choose this route in as many cases as possible.

Appearance of Ovum during Pregnancy

Dr. R. NEWTON (Manchester) read a preliminary communication on the appearance of the ovary during pregnancy. In October, 1928, Professor D. Dougal had described small, rusty-coloured areas on the surface of the ovaries as noted during Caesarean section. Dr. Newton had looked for these since in a series of Caesarean sections, and found them invariably present in both ovaries. He described the methods of fixing and staining employed, and demonstrated the microscopical findings in several specimens he had obtained. These rusty-coloured areas he found to consist of groups of decidua-like cells lying at varying depths in the cortex, but always with at least

three or four layers of cells separating them from the surface. The cells were apparently in every respect similar to decidual cells. They were large, oval, with faintly granular protoplasm and a prominent nucleus, lying in a loose matrix, with fibrils running between the cells. The presence of glycogen was demonstrated by Best's carmine stain. Dr. Newton stressed the point that he had not found any of these areas absolutely on the surface of the ovary, nor had he been able to find glands present in these decidual groups of cells.

The PRESIDENT, Professor D. DOUGAL, and Professor MILES PHILLIPS expressed the hope that Dr. Newton would continue what they considered likely to prove an investigation of the first importance.

CAESAREAN SECTION

At a meeting of the London Association of the Medical Women's Federation held on February 24th, with the president, Dr. LETITIA FAIRFIELD, in the chair, Mrs. IVENS-KNOWLES read a paper on the technique in low classical Caesarean section, and gave a résumé of results in 352 cases which had been under her care from 1919 to 1930. The development of the Caesarean operation was traced through the stages of its evolution, and the advantages and disadvantages of various suggested modifications were discussed. The cases recorded were consecutive ones. No craniotomy on a living child or panhysterectomy (except for fibroid tumours) had been performed during that period. Of the 352 cases, 99 were repeat operations—67 were for the second time, 25 for the third, and 7 for the fourth. It was possible at these repeat operations to make observations on the condition of the uterine scar and on the presence of intestinal or omental adhesions, from which conclusions might be drawn as to the relative safety or limitations of the classical operation. In 266 operations the indication was a contracted pelvis, with a total maternal mortality of 4—that is, 1.5 per cent. ; 168 were performed before or early in labour, with a mortality of 1.2 per cent. ; 66 late in labour (including cases of obstructed labour), with a mortality of 1.5 per cent. ; 24 after instrumental induction of premature labour, without mortality ; and 8 after attempted forceps delivery, with 1 death from *Staphylococcus aureus* septicaemia after two separate trials of forceps delivery. For eclampsia and other toxaemias 14 cases were operated on, with 1 death, and for accidental haemorrhage 5 cases, with 1 death. Central placenta praevia was the indication in 25 cases ; in this group, all the mothers survived, and only two infants were stillborn. Other conditions—namely, fibroid tumours, ovarian cysts, atresia of the cervix, excessive size of the foetus, brow presentation, advanced age of the mother, and bicornuate uterus—accounted for 27 cases, with no mortality. There were 10 cases of cardiac or pulmonary disease, with 1 death from sepsis, and a foetal mortality of 8.8 per cent. Of the total, 129 patients were primigravidae and 223 were multigravidae. Of the latter, 12 had previously had a craniotomy performed, and 40 had stillbirths—29 had one stillbirth, 10 had two, and 1 had three stillbirths. Cases operated upon early in labour showed a very low rate of morbidity, whereas cases of obstructed or protracted labour showed a morbidity rate of nearly 50 per cent. Two instances were known in which rupture occurred in a later pregnancy, both at about twenty-eight weeks, and both cases of advanced chronic nephritis. It was noteworthy that even in cases where the operation had been performed late in labour and the puerperium had been morbid the uterine scar was sound. Six cases were known to have stood, later, the test of vaginal delivery, two only requiring forceps.

After careful consideration of the results obtained, Mrs. Ivens-Knowles was of opinion that there was much to be said for the low classical operation, which is rapid, easy, and can be adopted for all cases, even when the head is firmly fixed as in a funnel pelvis. It was certainly advantageous to the child. A long enough time had not elapsed for statistics to show whether uterine rupture was less frequent after the lower segment operation, but cases had been reported by Ridler in which the upper segment scar held in a later pregnancy while the lower segment itself had ruptured, and the extraperitoneal operation appeared to be followed by a high morbidity rate from suppuration of the abdominal wound, uterine infection, phlegmasia alba dolens, and vesical fistulae. Recently a death from venous haemorrhage between the bladder and cervix in the transperitoneal operation had been recorded.

THE PSYCHIATRIC OUT-PATIENT CLINIC

At a meeting of the Royal Medico-Psychological Association held in the British Medical Association House on February 25th, with the president, Dr. T. SANTY GOOD, in the chair, Dr. IAN SKOTTOWE read a paper entitled "The utility of the psychiatric out-patient clinic." He referred first to Dr. Good's paper read at the annual meeting in 1921, which described the Oxford clinic. In the following year Dr. Ninian Bruce described Ministry of Pensions clinics. In the ensuing ten years these methods had been used at a number of clinics, legislation on the subject had been changed, and one of the primary aims of this paper was to record a number of small but important points which did not clearly emerge from formal reports. Pioneer work in this country was done by the late Dr. Henry Rayner, who set up a clinic at St. Thomas's Hospital about 1889, and gave his experiences at a meeting of the British Medical Association in 1893. In setting out the aims of his clinic, Dr. Rayner said that one purpose was to rid the public mind of the idea that mental disease was something apart from all other diseases. This broke down the isolation of alienism hitherto existing. The new Mental Treatment Act (Dr. Skottowe continued) brought the subject into sharp focus at the present time, as local authorities were empowered to open such clinics for the management of early cases. Two types of psychiatric clinic were already at work in this country: (1) the psychiatric institute type, the whole building being devoted to the in-patient and out-patient classes, the Maudsley Hospital and the Jordanburn Nerve Hospital being examples ; (2) the psychiatric out-patient department at a general hospital, usually run by members of the staff of a neighbouring mental hospital. In these out-patient departments it was surprising how few new cases were seen. Glasgow and Cardiff, concerned with large industrial populations, received only 100 to 120 new cases annually. The chief conclusion this probably pointed to was that, on the whole, neither the general public nor the family practitioner had realized that this consulting psychiatric service was so easily available. A wider publicity in Boston, U.S.A., resulted in 4,000 new cases of the kind annually, with no larger a population to draw from.

At Cardiff, the medical superintendent of the mental hospital was the senior consultant at the clinic, and he was assisted by the medical officers of the male and female sides of the mental hospital (a woman for the latter). The nurse at the clinic was a trained mental nurse from the mental hospital. The social worker was a fully trained person, and was in touch with the social conditions of the patients, as well as with the various social agencies. Each new patient was seen first by the senior psychiatrist, who made a preliminary survey of the case. Should organic disease be discovered, further investigation and treatment was arranged at a general hospital. Organic disease cases, however, formed only about 5 per cent. of the total. About 25 per cent. of the cases were obviously

fully developed mental cases—schizophrenia, mental deficiency, epilepsy with psychoses, etc. Usually the general practitioner knew that certification would be necessary, but it was a difficult class of case to handle, as the relatives would not consider the doctor's suggestion that the patient was mentally ill. Dr. Skottowe did not deprecate the sending of such cases to the clinic in the first instance, as even by a single consultation the clinic could render a real service to the practitioner, his patient, and the relatives. Dealing with less pronounced types, he said that 60 to 70 per cent. of the cases coming to the clinic were those of anxiety states, neurasthenia, hysteria, early depressions, and behaviour problems. Patients were always managed by a psychiatrist of their own sex. Concerning forms of therapy, he stressed the importance of the modern dynamic conception of mental illness, as one was dealing with individuals having peculiarly personal hopes, fears, beliefs, upbringings, who had met with a great obstruction in their lives. Apart from special physical measures, such as malaria and surgical operation where needed, the major forms of treatment available were psychotherapy and social service. Of the former, no particular school was adhered to, but Dejerine's "persuasionist" doctrines were chiefly used. Most of the patients were not of the deeply thoughtful class, and the psychotherapy must be of the common-sense order. Social service was not only valuable for collecting facts, but it had a definite therapeutic value. The out-patient clinic was primarily a utility organization, serving the needs of people whose lives were a tangle, who were mentally ill, but not ill enough to need mental hospital care.

Sir ROBERT ARMSTRONG-JONES said that when he started such a clinic at St. Bartholomew's he found that a definite proportion of the patients needed beds, and it was very difficult to ascertain the facts about the patients' home life, especially as the people themselves resented inquiries. There was now a better attitude towards mental illness, and this was greatly helped by the Mental Treatment Act of 1930.

Dr. F. R. P. TAYLOR expressed warm agreement with the contention that the medical officer from the local mental hospital should be attached to the clinic; it not only gave the patient confidence, but also ensured continuity of treatment if the patient should have to go to the mental hospital. Unless treatment could include bed accommodation the work was sure to be much limited and hampered.

Dr. W. DAWSON (Belfast) spoke of the favourable impression he had derived from a visit to Dr. Skottowe's clinic. He saw only the new cases, but they represented nearly all the leading forms of insanity or neurosis. The accommodation was adequate but not elaborate; it was such as any town with a general hospital could provide. He cordially believed in starting such clinics in conjunction with the local hospital; in most cases it would be impossible to provide a psychiatric clinic independently of the hospital. Moreover, the association ensured any kind of examination and thorough investigation of the patients.

Professor G. M. ROBERTSON said that this departure was one of the most hopeful and important which had taken place in the last generation. As Dr. Skottowe had stated, the numbers now coming to these clinics were not large, but every year showed an increased attendance figure as the existence and the value of such clinics became more widely known by the public, and the general practitioner knew more of their work. He agreed that the first interview with new patients was that from which students derived the greatest benefit. At Edinburgh the students who had taken out a course of psychiatry and medical psychology must subsequently attend the out-patient clinic, to take notes of the patients, and subsequently write a report on the cases seen. He also agreed that beds should be available for early mental cases; he estimated that one-fifth or one-sixth of the patients needed bed treatment. Almost all the troubles met with in regard to cases of mental disorder rested with certification.

Sir HUBERT BOND did not think public mental hospitals would get any voluntary patients, except a stray one here and there, unless there were a psychiatric out-patient department. The staff of the mental hospital should, he thought, be associated with the psychiatric out-patient clinic, though not necessarily as a dominant partner, as there might already be an honorary physician connected with the venture.

Dr. PERCY SMITH added his tribute to the pioneer work in this domain done by Dr. Rayner at St. Thomas's and Dr. Carswell in Scotland, and spoke of his own efforts in the same way at Charing Cross Hospital. Similar departments were now at work at St. Bartholomew's, Guy's, Westminster, Middlesex, and St. Mary's. At the Middlesex a small number of beds were allocated to these early mental cases, but not a special ward.

The PRESIDENT emphasized the importance of seeing medicine as one great whole; the work should be expanded in all directions. If these clinics were named psychiatric or mental it would, he feared, keep a large number of the people for whom they were meant from attending. In taking notes of these cases it must be remembered that the important aspect of a case was practically never that of which the patient made chief complaint. Everything possible should be done to encourage people to regard mental and physical conditions as one and the same.

Dr. J. G. SOUTAR noted with satisfaction that Dr. Skottowe was not wedded to any particular school of psychology; he recognized that there were a multitude of avenues of approach to the mind of the patient, and in consequence he did not marshal the facts about a patient as supporting any particular school, but as affording an insight into the patient's complexes.

Dr. MACRAE emphasized the importance of making mental hospitals as cheerful and comfortable as possible, so as to minimize the prejudice felt against such institutions. Some 95 per cent. of his patients were certified, but there were no grumbles, and the fact of certification seemed to possess no terrors. Relatives were shown round the wards, and seemed struck by the homelike appearance of the place; some regretted that asylum treatment had not been sought earlier. Most of the patients were inoffensive and not uncompanionable.

At the meeting of the Royal Society, on March 12th, a paper by Mr. E. W. FISH, on the reaction of the dental pulp to peripheral injury of the dentine, was communicated by Professor LOVATT EVANS. A series of earlier experiments in which diffusible dyes were placed in the pulps of human teeth indicated that when primary dentine was injured at the periphery, either by caries or attrition, the whole tract of affected tubules died and became walled off from the pulp by secondary dentine. The experiments upon which the report was based were carried out to investigate the nature of this reaction, and consisted in grinding a shallow cavity in the surface of the dentine and cutting serial sections of the teeth 2, 4, 8, 12, and 16 weeks later. The nature of the reaction varied with the severity of the lesion. The usual result was that the pulp ends of the injured tubules were sealed off by a deposit of calcium salts, and this was followed by a deposit of secondary dentine. The secondary dentine coincided exactly with the extent of the lesion, the injured tubules only being covered by it. The odontoblasts associated with the injured tubules underwent degeneration and most of them died; a proportion survived, showing regenerative changes, and laid down the tubules in the secondary dentine. When, as sometimes happened, all the odontoblasts died, under the affected tubules hyaline secondary dentine was formed, and large connective tissue cells with single nucleoli were found at the edge of the forming secondary dentine. A frequent result of cutting an experimental cavity in normal dentine was the production of small haemorrhages in the general pulp tissue, which persisted for some months, showing only a slight round-cell infiltration.

Reviews

HISTORY OF PAEDIATRICS

In the preface to his *History of Paediatrics*[1] Dr. STILL has told us something of the genesis of the volume: that it had its origin in the preparation of his FitzPatrick Lectures at the Royal College of Physicians. We read that he started on this enterprise a little more than two years ago. In that short space of time he has succeeded in producing a survey of his subject which is the first attempt in England to explore this field of medical history. Dr. Still himself reminds us of the work of John Ruhrah of Baltimore; and there is no one acquainted with Ruhrah's *Paediatrics of the Past* but would re-echo Dr. Still's epithets—"masterly and delightful." Still's work, however, is, as we have just now indicated, cast on somewhat different lines. It is his aim to produce an ordered account of the evolution of paediatrics, especially in England, since its early beginnings in the sixteenth century. To accomplish this aim he must needs give us some review of the state of knowledge at the time when our ancestors began to take a special interest in the subject, and therefore his earliest chapters deal with Greece and Rome, with the Arabians and the mediaeval Italians, before he can present to us the atmosphere in which Thomas Phaer conceived his *Boke of Children*. From this point the author moves onward through the next three centuries, showing the progress of knowledge not only in this country, but on the Continent—an ordered progress tracing the gradual emancipation of the medical mind from the traditional learning of the distant past till he leaves us at the dawn of the nineteenth century. Such an achievement is in itself remarkable, but its magnitude can only be appreciated when one has read the book and realized what has gone to its building. Dr. Still has always been known to his fellows as a scholar and a man of curious learning, but this volume must have meant to him hours of research and literary toil such as few but himself are fitted to undertake. On almost every page the reader who knows anything at all of medical history will recognize the evidence of careful examination of the original sources and critical appreciation of the attainments of the older writers, with due allowance made (and what store of knowledge this implies!) to the atmosphere in which they wrote. All who know Dr. Still will feel little surprise, because his passion for accuracy, his economy of statement, and his balanced judgement are familiar; but even so, they may well wonder how he has in so brief a period absorbed so large a mass of material, reduced it to order, and set it forth in so terse and yet conclusive a form.

The first impression, then, which is left on the reader is admiration for the scope and magnitude of the achievement. The next is perhaps a faint regret that the canvas was spread so large. So long as Dr. Still is strictly faithful to his main design, even he can fail to draw in sufficient detail to make the past live again for us. It is chiefly when he is (as no doubt he would express it himself) betrayed into digressions that he can give a living charm to his pages. In the earlier chapters one of the most delightful features of the book is the felicitous translation from foreign tongues. Whether these are all the work of the author we are not told, but at least the verse translations from the Latin are so skilful and so exact, and yet so melodious, that we cannot be wrong in attributing them to his classical taste. In other pages he has permitted himself to stray slightly from his main theme and consider the ideas of our forefathers on the education, the feeding, and the clothing of their progeny. For our part we could have wished even a larger licence. Just as in the exploration of a buried site the most accurate scientific observations are essential to the proper estimation of the value of the finds, and yet require selection, and even speculation, before they can take their ordered place in the elucidation of the site, so in a scientific history the real significance of many records requires a running commentary before they can combine into a picture. It is here that Dr. Still's scheme has, we believe, proved something of a drawback to the completed design. We could spare something of the dead words if we were given more of the living picture. What Dr. Still can do in that way is shown well by his sketch of Dr. Whistler. It is in such digressions that the student of humanity triumphs over the encyclopaedic historian.

It remains to add that anyone who desires accurate information upon the history of paediatrics will find no point neglected; that the detail compressed by Dr. Still's learning into a small compass may well be called minute; that the illustrations, though few, are good; and that at least one reader cherishes the hope that Dr. Still will shortly use this, and no doubt new matter as well, in a book of a design which will allow the poet and the story-teller in him to get the better of the scientific historian.

DISEASES AND INJURIES OF THE EYE

Dr. SYM'S *Diseases and Injuries of the Eye*,[2] which was first published in 1915, has now appeared in its third edition. It is a readable manual of convenient size for the public for which it is written—the medical student and the general practitioner. Omitting the introductory chapters on anatomy, which are found in most books of this kind, the author opens with a very useful chapter on the general examination of the eye and a discussion of the significance of the main symptoms presented by ophthalmological patients. Refraction is then dealt with, and there follows a series of chapters on systematic diseases and injuries of the eye and its adnexa, and operative technique. Two very useful chapters deal with medico-legal questions and points in the nursing of patients suffering from diseases of the eye—unusual features in a student's handbook, but extremely valuable. The book concludes with a chapter on therapeutic agents, and another on the visual requirements for the public services.

In so far as it is a book intended primarily for the instruction of students there are some small points to which attention might well be drawn. It is surely a mistake to speak of the tarsal plates in the lids as cartilages when they have no resemblance to this type of structure, but are composed entirely of fibrous tissue; and most authorities are agreed that a chalazion is not usually a retention cyst, but is rather of a granulomatous nature following a mild infection. Further, in order to obtain anaesthesia in operations on the lids we would feel safer with the use of novocain as an injection than with cocaine, as is recommended. It might also be debatable whether slitting of the canaliculus should be recommended without qualifications for the treatment of epiphora. Among embryological questions it is perhaps misleading to speak of cryptophthalmus as a fusion of the lids over the globe of the eye, or of the pupillary membrane as being formed by a persistence of the endothelium of the iris which at one time stretched across the pupil; while many would deny that all colobomata (of the iris, ciliary body, fundus, and optic nerve) are due to an aberration of the development of the vascular tissues of the uvea.

[1] *The History of Paediatrics.* By George Frederic Still, M.D., Hon. LL.D.Ed., F.R.C.P. London: Milford, Oxford University Press. 1931. (Pp. xxiii + 526; illustrated 25s. net.)

[2] *Diseases and Injuries of the Eye.* By William George Sym, M.D., F.R.C.S.Ed. Third edition. The Edinburgh Medical Series. London: A. and C. Black, Ltd. 1930. (Pp. xvi + 493; 87 figures, 24 plates. 12s. 6d. net.)

In the treatment of detachment of the retina, while operative procedures of any kind are discounted, the author suggests that the presence of a retinal hole aids the process of resolution by allowing the subretinal fluid to escape, which is not the experience of many ophthalmologists. Finally, no mention is made of arterio-sclerotic retinitis, and it must be admitted that in general practice the ocular manifestations of arterio-sclerosis are of clinical importance.

PRACTICE OF GYNAECOLOGY

The sixth edition of Dr. JELLETT's *Short Practice of Gynaecology*[3] has been edited by Professor R. E. TOTTENHAM of the University of Hong-Kong. In its general arrangement this edition follows its predecessors, but it has been brought up to date in many respects. It is doubtful, however, whether a book consisting of 512 large pages can justifiably be called a " short " practice of gynaecology. It seems doubtful also whether in any book addressed primarily to students and practitioners so much space ought to be devoted to the description of various methods of performing operations. The operative section occupies about 140 pages, and is most beautifully illustrated with the type of illustration that makes the operative procedure seem to the uninitiated a matter of tempting ease. Several of the operations described are not commonly practised, and some of them are certainly procedures which should not be attempted by anyone who is inexperienced in gynaecological operating, as, for example, the Mayo operation for prolapse as modified by Kelly. This is an admirable operation, but a description of it might well be relegated to what is avowedly a full treatise on gynaecology.

In the section on menstruation Professor Tottenham describes the menstrual cycle as beginning with the interval stage. The usual method of dating the beginning of the cycle from the beginning of menstruation seems to him illogical. But inasmuch as he states that " it begins *approximately about the fifth day* after the cessation of the last menstrual period " (the italics are ours), it seems that his method is still more illogical, as the starting point is so indefinite. Furthermore, this teaching, being at variance with that usually adopted, is likely to lead his students and readers into confusion in regard to what they find in other textbooks and writings. The section on cystoscopy may also be challenged, because that is a subject not usually regarded as coming within the scope of gynaecology; and the devotion of two pages to ureteral stricture is uncalled for. This is a condition whose very existence, except as a rarity, is denied by many competent urologists, and its detection and treatment are certainly matters only for one long practised in such work.

So far our criticisms have been concerned mainly with the amplitude of the fare provided, and, where there is so much that is really excellent, fault-finding is an ungrateful task, but the chapter on displacements of the uterus seems to us to call for adverse comment. The authors make a great deal too much of the mere matter of position, and when it comes to describing conditions such as " sinistro-version " or " dextro-version," or even worse, " sinistro-version with dextro-flexion," one feels as if one were reading a textbook of the period which called forth Clifford Allbutt's famous satire. Most British gynaecologists, at any rate, will disagree with the statement that " as a general rule it is advisable to adopt either operative or radical treatment in most cases in which a retrodeviation of the uterus is met with. Even if the displacement is not at the moment giving rise to any symptoms it will most probably do so in the future. . . ." We have found in the book no statement of the many conditions and circumstances in which a backward displacement needs no treatment whatsoever. It is a great pity that this chapter has not been brought into line with modern thought on the subject of displacements of the uterus.

[3] *A Short Practice of Gynaecology*. By Henry Jellett, M.D., F.R.C.P.I., and Richard E. Tottenham, M.D., F.R.C.P.I. Sixth edition. London: J. and A. Churchill. 1930. (Pp. x + 525; 360 figures, 4 plates. 21s.)

NUTRITION AND FOOD CHEMISTRY

In his preface to *Nutrition and Food Chemistry*[4] Dr. BRONSON says that the book was written primarily for classes of students possessing very little knowledge of physiology and none of organic chemistry. If that be so, we must conclude that the American student is much brighter than his English counterpart, for it contains a detailed and fairly advanced study of nutrition, and of those parts of biochemistry which bear on the different phases of the subject. Indeed, we doubt whether many medical students, at the end of their pre-clinical studies, would care to face an exhaustive examination on the subject-matter of this book. We should prefer to consider it, not as a medium of instruction for students with a slender groundwork of chemical and physiological knowledge, but as a textbook, suitable for reference rather than for continuous reading, addressed to medical men and senior medical students, and those making a special study of dietetics. For such it would be eminently useful. It treats quite adequately the modern facts of nutrition and of food chemistry, and the author has contrived to embody much very recent work. The data have, of necessity, been presented in the form of definite statements. There is no space in a book of less than 500 pages for lengthy criticism or for the weighing of evidence; this must be supplied by the reader himself. Since much of the matter is still more or less controversial, a critical spirit is highly desirable. We say this with no intention of reflecting on the accuracy of the author's statements or on the soundness of his judgement. A book that includes an account of most of the recent developments of a large subject must contain a certain number of statements which will have to be contradicted or modified within a few years. Outstanding examples are the sections on vitamins, on the chemistry of muscle, and on the role of phosphorus.

In science, as in other departments of life, America is evolving for herself a new language. To the English reader it is not always pleasing and is sometimes obscure. The book under consideration exemplifies this. So long, however, as it is not claimed to be " English," we have no right to complain. Dr. Bronson deserves congratulations on having brought to a successful issue a difficult and laborious task, which it must have needed no little courage to undertake.

THE ART OF PROLONGING LIFE

In *Pour vivre cent ans, ou l'art de prolonger ses jours*[5] Dr. A. GUÉNIOT, president of the Académie de Médecine of Paris in 1906, writes with the authority of good health in his ninety-ninth year about a subject upon which C. W. Hufeland and Sir Hermann Weber in the last century had published books with almost the same title. He believes that a hundred years is the natural term of years, and with the mellowed experience of a long and distinguished medical life does not exclude the enjoyment of tobacco or alcohol, in strict moderation, from the amenities of existence. There are many interesting accounts of centenarians, such as the eminent chemist Chevreul, who might have been a multi-millionaire had

[4] *Nutrition and Food Chemistry*. By Barnard S. Bronson. New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd. 1930. (Pp. viii + 467; 34 figures. 18s. 6d. net.)

[5] *Pour vivre cent ans, ou l'art de prolonger ses jours*. Par le Dr. A. Guéniot. Paris: J. B. Baillière et fils. 1931. (Pp. 205. 14 fr.)

he patented his discoveries; it is to be hoped that our author will surpass his fellow-countryman's 103 years. He quotes this remarkable example of hereditary old age: On July 31st, 1554, Cardinal Armagnac found a man of 81 crying in the street, and on inquiry was informed that his father, aged 113 years, had whipped him for failing to salute, when they met, his grandfather, aged 143 years. The influence of the endocrine glands is discussed, and a very cautious attitude is adopted with regard to Voronoff's operation. The book is full of sound common sense, and this is especially concentrated in a chapter on the code of longevity or rules for reaching the natural tale of days.

NOTES ON BOOKS

Although the title of BALLENGER'S *Diseases of the Nose, Throat, and Ear*[6] has not been changed for the sixth edition, the section on the ear is now placed first. This rearrangement is appropriate because that section has always been the most important and carried the greatest authority, and it remains so, although a complete revision of the whole book has been undertaken. Dr. Alfred Lewy has rewritten the chapters relating to the labyrinth, and gives a helpful account of the problems in diagnosis and treatment which beset this complicated and controversial subject. The book has also been strengthened at the other end by separate chapters on direct laryngoscopy, bronchoscopy, and oesophagoscopy by Dr. Gabriel Tucker and Dr. Chevalier L. Jackson. This presents in concise but adequate form the teaching of the Philadelphia Bronchoscopic Clinic. The main body of the book remains unaltered in style and spirit, although it has been revised throughout. This revision has been accomplished rather unevenly, so that the latest opinions on one point are sometimes found adjacent to paragraphs which have not been touched since the first edition. This inequality suggests that the plan of calling upon special contributors might be extended still further with advantage. The editor, however, has grappled with the difficulties of selecting new material and eliminating the old with a large measure of success, and the new edition will surely retain the place which the book has long held among the larger treatises of its kind.

The nineteenth volume of *Annali di Clinica Medica e di Medicina Sperimentale* consisting of 853 pages is dedicated to its founder, Dr. Liborio Giuffrè, professor of clinical medicine at Palermo. It contains fifty-one papers dealing mainly with various aspects of tuberculosis, metabolic and digestive disorders, and neuropathology. A portrait of Professor Giuffrè and a sketch of his career by Professor A. Pitini are prefixed to the volume.

The Leper's Cross,[7] by Dr. DENIS MULDER, director of the Radiological Institute at Bandoeng, Java, contains an account of the thirty years' campaign against leprosy in Java, together with the first report of the Light Institute, founded by the late Mr. K. A. R. Bosscha, a wealthy planter, at the Salvation Army's Plantoengan Leper Colony. A series of photographs is reproduced showing the improvement following the light treatment.

Inspection of the *Medical Register* for 1931 reveals that 1,490 names were added last year. New registrations numbered 768 in England, 350 in Scotland, 164 in Ireland, and 208 in the Colonies and abroad. This total exceeds the corresponding figure for 1929 by 80. Membership of the medical profession was 55,291 at the end of 1930, an increase of 421. The number of names removed from the *Register* during the year was 1,105, compared with 920 in the preceding year. Of these, 887 were removed on evidence of death, 214 for failure to comply with the inquiries of the registrar as to cessation of practice or change of address, and 4 were struck off under the disciplinary powers conferred by the Medical Act.

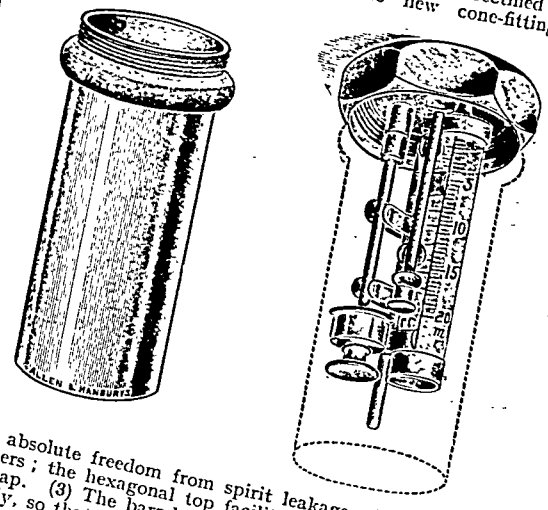
The number of dentists appearing on the *Dentists Register* for 1931 is 14,422, of whom 7,136, or 49.48 per cent., are registered with medical, surgical, or dental qualifications, compared with 6,825, or 47.46 per cent., so registered in the previous year out of a total of 14,381. Of the 280 British registrations that were added to the *Register* during 1930, 253 were registered with qualifications, and 27 under the Dentists Act of 1921—increases of 5 and 2 respectively. The number of names restored during the year was 306, and the number removed through death and other causes was 548. As formerly, the *Register* contains a local address list.

The *Medical and Dental Students Register*, issued by the General Medical Council, records that the number of medical students registered in 1930 was 1,792—290 more than in the previous year. Scottish registrations numbered 662, an increase of 36; English registrations 791, an increase of 161; and Irish registrations 339, an increase of 93. Dental students registered in 1930 numbered 306, which exceeds by 8 the figure of the previous year.

PREPARATIONS AND APPLIANCES

A SYRINGE CASE.

Mr. MILROY PAUL, F.R.C.S. (Ceylon Medical Service), writes: Messrs. Allen and Hanburys of Wigmore Street, W.1, have made to my specification a syringe case (illustrated herewith) which has the following advantages: (1) It is an all-metal nickel-plated case intended to be filled with rectified spirits, to sterilize the contents. (2) The new cone-fitting cap



ensures absolute freedom from spirit leakage without the use of washers; the hexagonal top facilitates opening and closing of the cap. (3) The barrel, piston, and needles are mounted separately, so that there is no possibility of the piston getting stuck in the barrel if the syringe is not used frequently. (4) In use the cap is unscrewed and placed on the table upside down, when it will act as a stand on which the components of the syringe are mounted. The pillar of the stand is attached to the cap, so that the withdrawal of the cap removes the components of the syringe at the same time.

AN ARTIFICIAL SUNLIGHT GENERATOR

We have received from the General Radiological and Surgical Apparatus Company, Limited (204–6, Great Portland Street, W.), particulars of the Neron Vitalux sunlight generator which they are placing on the British market. It is claimed for this lamp that it is "practically equivalent to natural sunlight." It is a hot filament lamp with a blue frosted glass bulb which is permeable, not only to light and heat, but also to the therapeutically active ultra-violet rays emitted by the filament. With the lamp is a reflector, which collects the spread of rays and concentrates them on a given area. The models, in stand and table form, can be connected to any plug carrying six or more amperes, the lamp consuming only 500 watts; the initial cost also is low. The lamp is not designed for the treatment of skin diseases, where a rapid "provocative" treatment with a high concentration of ultra-violet radiation, far exceeding that of sunlight, is called for, but it is offered for conditions in which mild ultra-violet radiation combined with light and heat rays—in other words, a sunlike emission—is desired.

THE INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF BLINDNESS

BY

A. BERNARD CRIDLAND, F.R.C.S.Ed., D.O.Oxon.

WOLVERHAMPTON

(British Representative on the Executive Committee)

The International Association for the Prevention of Blindness was founded and held its first session on September 14th, 1929, at a meeting of ophthalmic surgeons and others interested, at Scheveningen, Holland, on the conclusion of the International Congress of Ophthalmology, which had taken place there and at Amsterdam.

It had been in the minds of a number of ophthalmic surgeons of international repute that the time had arrived when a concerted attempt by all nations should be made to combat the affliction of blindness throughout the world. Although much in this direction has been achieved in the past, yet much more awaits accomplishment, as will be realized later in this article. At the outset, it may perhaps be of interest to recall briefly the attempts that have already been made to reduce the incidence of blindness generally.

It is with some satisfaction that it can be said that the first organized attempt was the formation of the London Society for the Prevention of Blindness about fifty years ago, at about the same time that Crédé's great work on ophthalmia neonatorum became known, and the first task that this society attempted was to make known the value of this epoch-making discovery. Its next step was to offer, at the fourth International Congress of Hygiene in 1882, a generous money prize for the best essay on the prevention of blindness; this was awarded at the fifth congress in 1884 to the late Professor Ernst Fuchs, at that time of Liége and later of Vienna, and his essay stands to the present day as one of the best papers on the subject.

Popular interest in the matter then appeared to wane, although much work was being carried on quietly by the medical profession itself in all the more civilized countries, Great Britain bearing its full share. Then in 1903, and again in 1906, American legislation took a hand by making an investigation into the condition of the blind and the causes of blindness in the State of New York. In 1908 Bishop Harman, in this country, established "myopia schools," in which special education was carried out for children suffering from progressive high myopia and defective sight from other causes.

In 1909 the notification of cases of ophthalmia neonatorum was made compulsory in Stoke-on-Trent and a little later in the county of Staffordshire generally, the rest of the country following. In 1914, owing largely to the foresight and energy of a great philanthropic lady, Miss Louisa Lee Schuyler, the United States National Committee (now Society) for the Prevention of Blindness, an entirely voluntary organization, was founded, and has progressed with such success that now, with a membership of 25,000 and an annual budget of 140,000 dollars a year, it stands as an example to all civilized countries.

In 1918 the Council of British Ophthalmologists was formed, its task being to act as an authoritative and representative body to assist Government departments and other representative bodies in, among other things, measures for the preservation and welfare of the eyesight of the community. Space does not permit me to detail the valuable and comprehensive work the council has already accomplished in the twelve years of its existence and what is expected of it in the future.

In 1922, in this country, the Departmental Committee on the Causes and Prevention of Blindness published its second and final report, a work which has been accepted as authoritative throughout the world. In 1924 the International Association for the Prevention of Blindness in China was formed, and the task which lies before it is tremendous. In the same year Dr. Park Lewis, vice-president of the United States Society for the Prevention of Blindness, delivered an interesting address at the Oxford Ophthalmological Congress, in which he put forward a plea for international co-operation. In 1925 Mr. Treacher Collins, the honorary president of the International Congress of Ophthalmology, made the elimination of eye disease the subject of his address when presiding in London over the Congress of English-speaking Ophthalmological Societies, and at the conclusion urged that "international co-operation against a common foe such as disease is the most likely way to secure international peace."

INAUGURAL MEETING IN HOLLAND

In 1928 and 1929 a provisional committee studied the possibilities of international co-operation for the prevention of blindness, and decided that the time had arrived for a definite movement of an international character towards this end. Accordingly the meeting referred to at the commencement of this article was convened by this provisional committee, acting with the League of Red Cross Societies and the American Society for the Prevention of Blindness.

Twenty-six different nations were represented on September 14th, 1929, by delegates from Red Cross Societies, societies concerned with public hygiene, infant welfare, prevention of venereal disease, and ophthalmology under the presidency of General Van Diehl of the Red Cross Society of the Netherlands. After a welcome by the president, the chairman of the provisional committee, Professor de Lapersonne (Paris), delivered an address, indicating the extent to which blindness is prevalent throughout the world, and urging the need for an international effort to combat blindness, especially in countries in which little or nothing has so far been done.

After speeches by Dr. Park Lewis (vice-president of the American National Society for the Prevention of Blindness); the late Professor Fuchs; Dr. Josephus Jitta (Health Section of the League of Nations); Professor Van der Hoeve (Netherlands), president of the thirteenth International Ophthalmological Congress; Dr. Humbert (secretary of the provisional committee); Mademoiselle Ferrière (Switzerland), representing the International Emigration Service; Dr. Cavaillon (France), secretary-general of the International Union against Venereal Diseases; and Mr. Gordon Berry, representative of the Near East Relief Association and the Golden Rule Foundation, Professor de Lapersonne then put the following resolution:

> After two preliminary meetings held in 1928 and 1929 by a provisional committee studying the possibilities of international co-operation for the prevention of blindness, and after consideration by this committee and other interested persons of the report published by the League of Red Cross Societies, the meeting composed of the provisional committee and other persons invited by the committee at Scheveningen, September 14th, 1929, recognizes the utility of constituting a permanent organization. This meeting, placed like the provisional committee, under the chairmanship of Professor de Lapersonne, Paris, recommends the formation of an International Association for the Prevention of Blindness.

This resolution was carried unanimously.

The officers of the association, together with the executive committee, were then elected as follows:

President, Professor de Lapersonne (France); vice-president, Dr. Park Lewis (United States of America); secretary-general, Dr. F. Humbert (Switzerland); treasurer, Monsieur Demachy (treasurer of the League of Red Cross Societies); and Professor von Szily (Germany), Dr. Roffo (Argentine), Professor Van Duyse (Belgium), Professor Marquez (Spain), Dr. Cridland (Great Britain), Professor Trantas (Greece), Professor Van der Hoeve (Holland), Professor de Grosz (Hungary), Professor Maggiore (Italy), Dr. Shinobu Ishihara (Japan), Dr. Villarreal (Mexico), and Professor Szymanski (Poland).

CONSTITUTION OF THE ASSOCIATION

A draft of the statutes of the new organization was then considered, and after some amendment a series of fifteen Articles were agreed upon, defining the objects, constitution, and procedure of the International Association for the Prevention of Blindness. The objects of the association are:

(*a*) To study through international investigations the causes, direct and indirect, which may result in blindness or impaired vision.

(*b*) To encourage and promote measures calculated to eliminate such causes.

(*c*) To disseminate knowledge on all matters pertaining to the care and use of the eyes.

The direction of the association is in the hands of a governing body.

The governing body may form, from its own members, medical or non-medical, technical subcommittees, to prepare and present technical advice, upon which the association may act. For the study of all scientific questions the majority of the subcommittees must be composed of ophthalmologists. For the general supervision of the work of the association in the intervals between annual meetings there is an executive committee, composed of the chairman, vice-chairman, and at least five members chosen from different nationalities, and able to meet at regular intervals.

The secretary-general and the honorary treasurer are *ex-officio* members of the executive committee. Article X provides that the executive committee shall have all the administrative and financial powers of the governing body, to whom it transfers its authority when not in session. An official report, including a detailed account of income and expenditure, shall be published yearly by the executive committee and submitted to each meeting of the governing body. Article XII provides for the establishment of a permanent secretariat, whose organization and work shall be directed by the secretary-general, subject to the instructions by the chairman and decisions of the governing body. The functions of the secretariat as defined in Article XIII are to:

(*a*) Act as a clearing-house for all national or local agencies interested primarily in sight conservation.

(*b*) Provide information to agencies indirectly concerned, which may wish to include prevention of blindness as part of a larger programme.

(*c*) Collect, evaluate, and consider information concerning all public and voluntary activities for the prevention of blindness; summarize publications, possibly publishing a periodical which may be distributed to all agencies interested in sight saving; issue translations in current languages of material believed to be of value.

(*d*) Suggest legislation and regulation.

(*e*) Promote international, national, and local organization, dealing with the preservation of sight.

(*f*) Promote research as to the causes of blindness.

(*g*) Undertake all necessary steps to provide resources for the association.

Article XIV provides that the headquarters of the association shall be located in Paris for the present.

At the conclusion of the inaugural meeting it was decided that the executive committee of the association should formulate a general appeal to be circulated in all countries of the world, and signed by all members of the executive committee.

RECENT PROGRESS

The second annual meeting of the board of governors was held on October 10th, 1930, at the Palais des Académies in Brussels. Professor de Lapersonne was supported by the members of the executive committee and of the bureau of the secretariat, and there were also present representatives of many sympathetic societies, which have become affiliated to the association, together with a number of well-wishers. The morning was occupied by administrative matters, and in his presidential address, Professor de Lapersonne stated that the work of the association in this, the initial stage of its career, had been conducted on three main lines, as follows: first, in the endeavour to find people who were in sympathy with the work and who might help; secondly, in the preparation and issue of a world-wide appeal, together with plans for the organization of national committees; and thirdly, in the study of several medico-social problems which come within the compass of the association's programme. With reference to the first, many people had come forward with offers of help, while support and approval had been received from different countries. Under the third heading, an inquiry was being made into industrial eye accidents by ophthalmologists practising in industrial areas. In France this work was being carried on in conjunction with the General Insurance Companies Committee, which included all the insurance companies of that country, and it had already yielded much valuable information. A report on sight-saving classes for children had been drawn up and presented to various public bodies, and further work in this direction was being carried out. Finally, the association was represented, with voting rights, on the executive committee of the Anti-Trachoma League, so that these two bodies would work together without trespassing on each other's spheres of action.

The general secretary, Dr. Humbert, then presented his report, in which he referred to the time of financial difficulty at which the association had come into being, and it was on this account that the issue of the world appeal had not been generally made, but only issued to a limited number of well-wishers. The response to this, almost wholly from members of the medical profession, had been generous. Twenty-three national Red Cross societies had now adhered to the association, and the United States National Society for the Prevention of Blindness had voted a contribution of 1,000 dollars, besides its annual subscription. In conclusion, Dr. Humbert laid the greatest stress on propaganda as the key-note, not only in the work of the association, but in creating the means by which its work can be carried on.

A very interesting address was then delivered by Mr. C. J. Henderson, the president of the All-India Blind Relief Association (the Green Star Society), in which he showed clearly the enormous field of work in India that lay waiting to be attacked. Blindness in that country is, according to more detailed inquiry, something like three times the amount that the official census returns give, and must total quite a million and a half, much of which can be prevented. The conditions in China were then described by Dr. Lossouarn of the School of Medicine, Tientsin. It was impossible not to be impressed with the need for help in that country. Dr. Lossouarn's investigations show that half a million have lost their sight in China from small-pox alone, constituting 35 per cent. of the total number of blind. Xerosis from faulty hygiene ranks next, although it must be presumed that this is a temporary cause only. Trachoma is the third numerical cause, followed by syphilis (50 per cent. of the population in the towns are infected) and gonorrhoea, whilst a common cause is injury to an eye by the pricking of any part of the organ by a relative or quack.

The afternoon was mainly occupied by scientific papers, the first of which was a report by the president, giving the results of an inquiry made by the association into industrial accidents. The information obtained so far has emphasized the considerable part played by these accidents as a cause of unilateral or total blindness, and has shown that the proportion is increasing with the progress of industry, as might be expected. Professor de Lapersonne then spoke on sight-saving classes for children with defective vision. After paying a well-deserved tribute to the pioneer work of Mr. Bishop Harman—who in 1908 in London was the first to establish a class of this kind—he referred to what had followed in Germany and the United States. Mr. Lewis Carris, speaking from his long experience as a school administrator, gave an account of similar work which was being done in the United States. There they had recognized the need for extending the benefit of this special education to country children, among whom defective sight was more prevalent than in town children, for reasons not yet satisfactorily explained.

The session concluded with an address on trachoma by Professor Angelucci (Naples), in which he discussed the relationship of trachoma, follicular conjunctivitis, and adenoidism. From the interest displayed throughout the meeting it may be concluded that the association has made an excellent start. As the result of the decision that the time for issuing the world appeal was inopportune on account of the general financial depression, it has been agreed that national committees should be set up in the affiliated countries, and a British committee is now in process of formation.

INTERNATIONAL ASSOCIATION FOR PREVENTION OF BLINDNESS

The International Association for the Prevention of Blindness, some details of which are given by Mr. Bernard Cridland in his paper appearing elsewhere in this issue of the *British Medical Journal* (p. 457), represents a united attempt on the part of ophthalmic surgeons of all nationalities, working in conjunction with the League of Red Cross Societies, to reduce the incidence of blindness throughout the world, particularly in those countries in which but little is being done in this direction. Such a task must be recognized as gigantic, but a consideration of the facts will show that the attempt had to be made, and that the establishment of an association with this aim in view is fully justified.

According to the statistics now available, there are to-day some five million sightless human beings in the world, but this figure falls far short of the actual amount, for, where it has been possible to make a more detailed investigation, the number is found to be thrice as large, and probably it would be no exaggeration to say that from twelve to fifteen million is the more accurate estimate. If it was inevitable that this should happen, the recognition of the fact would probably be passed over with regret and sealed with the word "Kismet," but all who realize that at least 50 to 60 per cent. of this blindness need not have occurred must admit that such an effort as the International Association for the Prevention of Blindness is now making is long overdue, and will share our satisfaction that it has been begun. In attempting to grapple with a problem of these dimensions the first thing necessary to be considered is finance, and those who are willing to give will naturally want to know how the money is to be spent. The answer to their question is that the method must be one of propaganda. It would be impossible for an international body to say to any country, "You must take steps to prevent this blindness that is occurring among your people, and you must do so-and-so to put a stop to it." But it is possible to stimulate national interest in the incidence of this terrible disability, to encourage an investigation into its causes, to indicate hygienic measures for combating those causes, and to promote the formation of societies for the prevention of blindness in the countries where there are none at present, and, furthermore, to assist financially such societies as already exist. A good example of an existing body in need of help is afforded by the International League for the Prevention of Blindness in China; this was established in 1924, but Dr. Lossouarn, its vice-president, has stated that it will have to close down its activities and disappear unless financial aid is forthcoming. When it is remembered that the population of China is about 445 million, and that officially there are about three eye hospitals for the whole country, as compared with forty-eight eye hospitals for the forty-seven and a half million of population in Great Britain, Northern Ireland, and the Irish Free State, it will be seen that there is need for international stimulation and for remedial measures in China. There also remains much to be done in our own country in the direction of the prevention of industrial accidents to the eye, while a vast field of ophthalmic work lies open in India, our own particular care.

It is unfortunate that the International Association for the Prevention of Blindness should be launched at a time so unfavourable for any financial project; and it has been decided to postpone the world-wide appeal which it was intended to make in all countries simultaneously, and meanwhile to form a national committee in every country affiliated to the Association. The task before each committee will be to stimulate interest in the prevention of blindness, not only in the world generally, but more especially in its own country, and to seek financial aid. Funds collected in any country will go direct to the central bureau of the International Association in Paris, and will be allocated for use by the executive committee, but on the understanding that the contribution so made can be earmarked for use in the particular country and its dependencies, through the medium of its representative on that committee. The British committee is in process of formation.

TREATMENT OF CANCER OF THE BLADDER

The treatment of carcinoma of the bladder is at the present time profoundly unsatisfactory, and, for that reason no doubt, it has lately been very prominent in medical discussions both in this country and abroad. In the *Journal of the American Medical Association* of December 6th, 1930, appears a group of papers on various aspects of this important problem in genito-urinary surgery, read at the annual meeting in Detroit last summer. Dr. Herman L. Kretschmer of Chicago considers it from the point of view of surgical diathermy, Dr. George Gilbert Smith of Boston from that of diathermy supplemented by radium; Dr. B. S. Barringer of New York discusses treatment by radium alone; while Dr. Harold D. Caylor of Bluffton devotes himself to the pathology of the subject. Each writer supports his arguments by bringing forward statistics of the results obtained from the form of treatment with which his paper deals; and it is, of course, upon such evidence that a decision as to the value of any particular remedy must rest. But after studying these four papers the reader must conclude that a comparison of remedies for carcinoma of the bladder based on statistics is at present of little value owing to the difficulty of classifying vesical growths.

As Dr. Caylor points out, when the dividing line between malignant and benign tumours is approached,

their histological, and, still more, their clinical differentiation, becomes a matter of the very greatest difficulty. Consequently, in the statistical tables drawn up by different writers are included cases which would be excluded from those supplied by other authorities, and until greater precision is reached in the classification of bladder growths no statistical comparison of methods of treatment is possible. For this reason the method of grading epitheliomata, elaborated by A. C. Broders at intervals during the past ten years, has been a move in the right direction. His method is based on the completeness of the differentiation of the cells forming the tumour, for the more completely differentiated the cells the less is the malignancy of the growth. To quote Broders's words when discussing tumours of the bladder, "a neoplasm can accomplish only what its cells can accomplish; if its cells are active, it is active. A neoplasm may be of papillary form and of a low degree of malignancy, or it may be papillary and of a high degree of malignancy. It may be flat or ulcerated and of a high degree of malignancy, or it may be flat or ulcerated and of a low degree of malignancy."[1] A grading of bladder growths must therefore rest on histology rather than on clinical appearances, and hence the obtaining of a microscopical section would appear to be an essential preliminary to a decision as to what form of treatment is most likely to be successful. An objection may be raised that even the histological examination of a fragment removed from a growth is liable to error, owing to the fact that different portions of the tumour may exhibit different degrees of malignancy. Kenneth Frater, however, denies that this is the case. According to him there is no important variation in the grade of malignancy between the surface and the base of a bladder growth, and even when specimens are removed at different times from the same epithelioma no difference in the grade of malignancy is discoverable.

Returning to the subject of treatment, we are forced to agree with Dr. George Gilbert Smith when he says that no one method is suitable for all cases. Excision, electro-coagulation, and irradiation, all have their places. For growths occurring in a situation that permits of complete removal, excision is undoubtedly the method of choice; for those which cannot safely be removed by the knife, electro-coagulation or electro-coagulation supplemented by the implantation of radon seeds must be employed. Combining the statistics supplied by the different writers, it would appear that, for the time being, successful results are only to be expected in some 25 per cent. of cases of carcinoma of the bladder presenting themselves for treatment. It is of interest to note that among those patients who died immediately, and those who died in hospital as the result of treatment, the commonest cause of death appears to have been pulmonary complications. Even where treatment was by diathermy pulmonary trouble was responsible for the greatest number of deaths. Of twenty-five patients who died in hospital after open diathermy Dr. Kretschmer states that seven died as a result of pulmonary embolism, and four from pneumonia. Thus pulmonary complications were responsible for 44 per cent. of post-operative deaths. Next in importance as a cause of post-operative death were renal lesions, which accounted for 32 per cent. of the fatalities.

IODINE SUPPLY AND ENDEMIC GOITRE IN GREAT BRITAIN

Interest in the problem of the relation of the amount of iodine in the environment to the incidence of endemic goitre has been revived by the publication of researches carried out in America, New Zealand, Switzerland, and the Scandinavian countries since the war. Under modern conditions, with a mixed and moving population, and the constant interchange of foodstuffs in civilized communities, the error of statistical observations must be great when so many unknown factors are concerned. Nevertheless, though some discrepancies naturally occur, there is a general agreement which is rather striking, that in places where endemic goitre is prevalent the iodine content of the water, soil, and foodstuffs tends to be low. The Medical Research Council has taken measures since 1927 to investigate systematically the geographical distribution of goitre in this country, and particularly its relation to local deficiencies of iodine in drinking water and common foodstuffs. In a preliminary report just published, Dr. J. B. Orr[1] of the Rowett Research Institute, Aberdeen, gives the results of a survey undertaken to determine whether any striking difference between the iodine content of public water supplies and of locally grown foodstuffs occurred in goitre and non-goitre districts. Analyses of drinking water from the supplies of eleven towns or cities, and eight rural areas, showed no correlation between the concentration of iodine in the water and the incidence of goitre in the area from which it came. A similar result was obtained by Shore and Andrew[2] in a carefully conducted investigation of the conditions in the North Island of New Zealand, where in some districts goitre is endemic. Dr. Orr then turned his attention to the investigation of the iodine content of foodstuffs and of sheep thyroids. In choosing areas for the collection of samples use was made of the Board of Education survey of the incidence of goitre among school children. From this survey the counties of highest and lowest incidence were chosen: Somerset and Cornwall, high, and Essex, low. Other counties, too, were selected in which the county medical officers reported an abnormal goitre incidence. As an additional control samples were obtained from counties in the north-east of Scotland, where endemic goitre appears to be non-existent. Samples were taken of soil, pastures, milk, eggs, and vegetables, and the analyses were made by the same worker throughout, whose results were controlled by duplicate analyses made by one or other of two additional chemists. No precise survey was made of the incidence of goitre in the areas investigated. Nevertheless, there are indications that the iodine supply, as judged from analyses

[1] Medical Research Council. Special Report Series, No. 154. *Iodine Supply and the Incidence of Endemic Goitre.* By J. B. Orr. London: H. M. Stationery Office. 1931. (4d. net.)
[2] *British Medical Journal*, February 28th, 1931, p. 361.

of milk, eggs, and cabbage, is higher in the Scottish area which is known to be goitre-free, than in the English counties where goitre is, to a greater or less extent, endemic. On the other hand, there is no indication of any definite difference between those areas in England which were reported to have a low goitre incidence and those reported to have a high goitre incidence. Besides the results of the Board of Education survey of school children, the English counties were graded as to the incidence of goitre according to reports of the local medical officers of health, but, unfortunately, in this way no uniform basis of diagnosis could be used for correlation with the chemical findings. In the well-planned New Zealand observations of Shore and Andrew referred to above, the goitre statistics were as carefully compiled by one observer as the chemical analyses by one investigator. The results of Shore and Andrew pointed to a fairly close inverse relationship between the incidence of goitre and the amount of iodine in the soil.[1] Dr. Orr has also investigated the thyroids of sheep grazed in goitre and non-goitre districts, and his results suggest that a low level of thyroid iodine may be correlated with a low level in pasture and milk. A serious difficulty commented on by all workers on the subject is that of estimating iodine accurately in the presence of organic matter. The process of ashing the material in the course of chemical analysis involves a certain amount of loss of iodine. An improved standard method that will give results closely approximating to accuracy, or results in which the error is constant and known, is needed. The Medical Research Council has appointed a special committee of chemists to investigate this problem, and it is to be hoped that a standard method may be evolved which can be used in the study of all problems of iodine deficiency, whether in relation to endemic goitre or to the processes of health and disease in general.

A MEDICAL SURVEY OF CANADA

In 1929 the Council of the Canadian Medical Association at Montreal decided to send out a questionary to the medical profession in Canada with a view to discovering the conditions under which practice was being carried on in the various parts of the Dominion. Of 9,000 forms sent out 1,400 were returned completed, and this is judged to be very satisfactory in view of the fact that many of the recipients were engaged in full-time administrative work, had retired, or were otherwise not in a position to furnish the data asked for. The replies have been tabulated, and a report by Dr. Harvey Agnew, associate secretary of the C.M.A., was published in the January issue of its journal, one part dealing with the practice of medicine, and the other with medical education. Doctors in villages might have been expected to return a greater mileage than those practising in towns, but in Alberta, Saskatchewan, Quebec, and Prince Edward Island the reverse was found to be the case. Journeys for special consultations in towns and villages were affected very little by winter, except in Winnipeg, Montreal, Halifax, and Charlottetown. A curiously low mileage return for towns and villages in Ontario, and to a lesser extent in Quebec, New Brunswick, and the towns of Nova Scotia, is attributed to industrial practice and the custom in rural areas of patients travelling to consult the doctor, the existence of the small local rural hospital being a determining factor in this connexion. No serious shortage of doctors has been reported in any districts, but a few replies (1.7 per cent.) to this effect were received from village areas and one or two towns. From other sources it is known, however, that areas in the northern and more sparsely inhabited parts of some Provinces have little or no medical supervision, and are therefore not covered by these reports from medical practitioners. The problem appears to be how these areas can best be assisted, for it is undeniable that medical services are urgently required by the more pioneer districts and by certain village communities. Considering Canada as a whole, and analysing the returns on the urban-rural basis, the conclusion is reached that in large cities there is one doctor to 1,086 population ; in small cities one to 1,071 ; in towns one to 1,248 ; and in villages one to 1,346. As a whole the Dominion has 97 medical practitioners to 100,000 population, the comparable figures for doctors elsewhere being 127 in the United States, 80 in Switzerland, 73 in Japan and Hungary, 67 in England and Wales, 64 in Germany and Argentina, 59 in France, and 35 in Sweden. Good consultant service appears to be available in all the cities, whether large or small, but the towns are worse off, particularly in British Columbia. Each Province, however, reports a distinct shortage of hospital accommodation. Medical education in Canada was commended in the replies to the questionary, but a number of suggestions for its improvement were made, especially as regards the provision of more practical training in some subjects. In an editorial reference to this survey in the same issue of the *Canadian Medical Association Journal* it is noted that many of the young doctors are settling in the smaller towns and cities, but that two out of fifteen of those replying did not think that they were making a fair living a year ago. In the rural areas the consultation service is regarded as insufficient, and there is also a lack of laboratory and *x*-ray facilities. The C.M.A. is to be complimented on the valuable information it has obtained by conducting this inquiry, the benefits of which will be even more appreciable when the medical schools and local authorities have had time to assimilate the facts thus brought to light.

THE CENSUS AND THE COMMON HEALTH

As already announced in these columns the next census will be taken on April 26th, and the Government has been at pains to issue an official pamphlet[1] to show how a census discovers the social and economic condition of the people. Obviously certain matters, such as old-age pension administration and the provision of schools, depend upon a knowledge of the ages of the population, while other matters, such as those relating to unemployment, and health insurance, and compensation, require a knowledge of the number of persons engaged in various kinds of occupations. The census figures assist in the keeping of a watch upon the health of people living in various localities or engaged in certain trades, and with their aid it is possible to make effective comparisons whereby unhealthy localities and

[1] *Notes on Census-taking*. Prepared with the authority of the Registrar-General. Harrison and Sons, Ltd.

callings can be identified. The fact that one urban district shows a higher death rate per 1,000 living than another does not in itself prove very much, because in the area with the higher death rate there may be a larger number of old people. The census permits due allowance for age distribution to be made. It is possible by the same means to pick out occupations which have a death rate so much higher than others as to call for special attention. The census figures also serve as a basis for the distribution of Exchequer grants to local authorities for the provision of necessary services, as a measure by which the demand for public utilities and amenities can be gauged, as a means of reckoning the average consumption of commodities per head, and as an aid to estimating industrial and social conditions in different areas. In the multitude of figures the expert eye can detect changes or drifts in the habits, the customs, and the circumstances of the people, without some knowledge of which the efforts for betterment, however unselfishly and enthusiastically pursued, may be sadly misdirected. We are puzzled by one remark in this Government leaflet, where it is stated, speaking of the first census taken, in 1801, that the result "gave a total population for England and Wales of about 9 million. It is interesting to note that there was no disparity in the numbers of the sexes. The position was thus in marked contrast to the present excess of nearly 2 million females over males." But in 1801 the number of males in England and Wales was 4,254,735, and of females, 4,637,801, and the proportion of females, namely, 52.15 per cent. of the total population, was almost the same as the proportion in 1921, namely, 52.29 per cent., though in the meantime the population had multiplied by more than four. The exceptional effect of the war upon the male population is no doubt reflected in the 1921 figures; in 1911 the percentage of females was 51.6, almost exactly the same as the proportion a hundred years ago. The proportion of females to males, in fact, has remained fairly constant throughout the period covered by census-taking. Since the beginning of the nineteenth century, at any rate, there have always been in this country about 103 or 104 females to 100 males.

RIVER INVESTIGATIONS

While the self-purification of polluted rivers is well known to occur, there is at present a lack of exact information regarding the natural processes involved, and also regarding the quantities of polluting effluents from sewage works and other sources which may be received without damage. With a view to the acquisition of more precise knowledge on this subject the Water Pollution Research Board, as narrated in its report for the year ended June 30th, 1930,[1] has undertaken a scientific survey of the River Tees, which is regarded as a typical river flowing through an industrial community. The observations hitherto made have revealed the changes which take place in the composition of the river water, and in its fauna and its flora, under many conditions of tide and rainfall, from source to mouth. Another investigation of the Board has reference to the waste from beet sugar factories, a difficult problem to the settlement of which the researches of the Board have substantially contributed. The Board's view, as expressed in 1928, was that the ideal solution would be to discharge no beet sugar waste at all, and towards this end the Director of Water Pollution Research recommended the re-use of waste waters. As this plan involved some accumulation of substances in the re-used water it became necessary to contemplate the discharge of some portion of it, and the Board has shown that for the moiety of water so required to be discharged the necessary degree of purification can be effected by means of biological filters. The report refers also to the continuation of an inquiry concerning the base exchange or zeolite process of water softening, from which it emerges that under ordinary conditions the amount of silica taken up by the softened water is in most cases too small to be measured, and that the bacterial content of the water is unaffected.

THE DISCOVERY OF OXYGEN

A very just account of the events leading to the eighteenth century revolution in science is contained in Dr. A. N. Meldrum's critical study of the first phase of the movement—namely, that which terminated in the discovery of oxygen.[1] The respective parts played by the two principal actors in the movement, Lavoisier and Priestley, have been the subject of debate, but the conclusions reached by Dr. Meldrum after close consideration of the facts seem to be unexceptionable and to remove all obscurities. He portrays the two men as deeply engaged, during this first phase, in the study of gases, but studying them with very different objects, corresponding to an essential difference in their order of mind. Lavoisier, on the one hand, with prophetic insight, was convinced that a solution of the problem of combustion would result in a complete revolution in physical and chemical science. But the solution of the problem required the discovery of the particular gas which was concerned in the process of combustion. Hence, his interest in gases was limited to an endeavour to discover the one gas which would enable him to bring about the revolution of which he dreamed. Priestley, on the other hand, was interested in gases generally and for their own sake. He was able, apparently, to produce new gases at will, and was a master in their manipulation, but he had no idea of revolutioning the science. Among his new gases there was one, obtained by focusing the sun's rays on oxide of mercury, which evidently gave him peculiar satisfaction, for he writes:

"The most remarkable of all kinds of air that I have produced by this process is one that is five or six times better than common air, for the purposes of respiration, inflammation, and, I believe, every other use of common air. . . . I easily conjectured that inflammable air (hydrogen) would explode with more violence, and a louder report, by the help of dephlogisticated than of common air; but the effect far exceeded my expectations, and it never has failed to surprise every person before whom I have made the experiment. The dipping of a lighted candle into a jar filled with dephlogisticated air is alone a very beautiful experiment."

[1] *The Eighteenth Century Revolution in Science—The First Phase.* By Andrew Norman Meldrum, I.E.S., A.R.C.Sc., D.Sc. London and Bombay: Longmans, Green and Co., Ltd. 1930. (4s. 6d. net; Rs.3 net.)

Priestley playfully suggested that in time the gas might become a fashionable article of luxury, and he foresaw its medicinal utility as an inhalation in certain pulmonary affections. But to Lavoisier, to whom Priestley incidentally mentioned the discovery in the course of conversation, it bore a very different significance; it was the gas he was seeking, and he was thenceforth enabled to proceed with his scientific revolution, until his head was severed from his body by the other revolution then in progress. Priestley undoubtedly discovered oxygen; can it be said that Lavoisier discovered it independently? Lavoisier speaks with an uncertain voice on this point—he suggests that perhaps Priestley was before him. But Lavoisier was particularly careful to make records of all his experiments, and it seems unlikely that he would have failed to record the circumstances of a discovery so important to him as that of oxygen. No such record has, however, been forthcoming up to the present; but we can hardly doubt that, even if he had not then discovered the gas, he would ultimately have succeeded in doing so, for he knew what he was seeking, and was working on much the same lines as Priestley himself.

PORTRAITS OF SURGEONS

It needs the publication of a new *Catalogue of Portraits and Busts in the Royal College of Surgeons of England*[1] to remind us that besides its unrivalled anatomical and pathological possessions the College has no mean claim to notice on account of its collection of works of art. The former catalogue with short biographies published in 1892 is now out of print, and since that date the College has acquired a number of works, including fifteen portraits and two groups of the Council in 1884–5 and 1927–8. The Council, therefore, is to be applauded for authorizing the preparation of a revised catalogue with similar biographies of those who are no longer living, and for entrusting the work to the capable hands of Sir Frederick Hallett. Thirty-eight years have necessarily played havoc with the leaders of the profession of surgery, and Sir Frederick Hallett has had to provide biographical notes of many of the great Victorian surgeons. To take them as they come, alphabetically, Bowlby, Bryant, Butlin, Erichsen, Fergusson, Godlee, Heath, Holmes, Hulke, Hutchinson, Lister, MacCormac, Morris, Paget, Power, Savory, Spencer Wells, and Erasmus Wilson are all names which are not yet forgotten, and some of which will not be forgotten for generations to come. The busts at the College are particularly striking. Such portraits in marble as those of Lister and Paget bring their originals vividly before the eyes of the observer. This kind of portraiture may be sneered at by the modern school as "representative," but we venture to think that representative art alone is capable of raising up for us and our successors the expressions and personalities of the mighty dead of surgery. Among recent acquisitions of older paintings are those of the two Hunters. The fine portrait of William, by R. E. Pine, which was presented by Captain William Hunter Baillie in 1895, is here well reproduced. By the liberality of Mr. G. Buckston Browne in 1925 the College acquired an additional portrait, believed to be that of John. Among portraits of officials of the College is one by William Oliver of that great artist of the blackboard, and Conservator, Charles Stewart, and that by Onslow Ford of the Prosector, William Pearson, the representative of a family which has served the Museum for 145 years in three generations.

[1] *Catalogue of Portraits and Busts in the Royal College of Surgeons of England.* Revised to January, 1930. (Pp. 95. 3s.)

OXFORD OPHTHALMOLOGICAL CONGRESS

The twenty-first Oxford Ophthalmological Congress will be held, under the presidency of Mr. Bernard Cridland, on July 9th, 10th, and 11th. The members will assemble at Keble College on the evening of Wednesday, July 8th, and on the following morning there will be a symposium on "The diagnosis of intracranial new growths," to be introduced from the ophthalmological standpoint by Mr. Leslie Paton; from that of the neurological surgeon by Sir Percy Sargent; from the perimetric aspect by Dr. H. M. Traquair and Mr. Norman Dott of Edinburgh; and Professor Artur Schüller of Vienna will discuss the subject in connexion with radiology. In the afternoon Professor G. Elliot Smith will give an address on "The evolution of the instruments of vision." The Doyne Memorial Lecture will be delivered on the morning of July 10th by Mr. Philip E. H. Adams, Margaret Ogilvie Reader in Ophthalmology in Oxford University. Professor Bailliart of Paris will give an address on tonometry, and a discussion on penetrating wounds of the eyeball will be introduced by Mr. James Craig of Belfast and Professor Schüller. A number of independent papers have already been promised, and there will be demonstrations in the scientific and commercial museums. The annual dinner will take place in the Hall of Keble College on July 9th. The full programme of the congress is to be issued in June. All communications should be addressed to Mr. C. G. Russ Wood (12, St. John's Hill, Shrewsbury), who is again acting as honorary secretary.

CLIO MEDICA

In our issue of October 18th, 1930 (p. 655) we mentioned the series of primers on the history of medicine, which Professor E. B. Krumbhaar of Philadelphia is editing, under the general title of "Clio Medica." At that time three volumes had been issued—namely, *The Beginnings: Egypt and Assyria,* by Mr. Warren R. Dawson; *Medicine in the British Isles,* by Sir D'Arcy Power; and *Internal Medicine,* by Sir Humphry Rolleston. Two more have now been added to the series: *Anatomy,* by Dr. George W. Corner of the University of Rochester; and *Physiology,* by Dr. John F. Fulton, Sterling professor of physiology at Yale University. These handy little books, each written by an acknowledged authority, are published by Paul B. Hoeber, Inc., of New York, at the price of 1.50 dollars each.

We regret to announce the death of Dr. David Hepburn, C.M.G., Emeritus Professor of Anatomy in the University of Wales, and Past-President of the Anatomical Society of Great Britain and Ireland.

NINETY-NINTH ANNUAL MEETING
of the
British Medical Association
EASTBOURNE, 1931

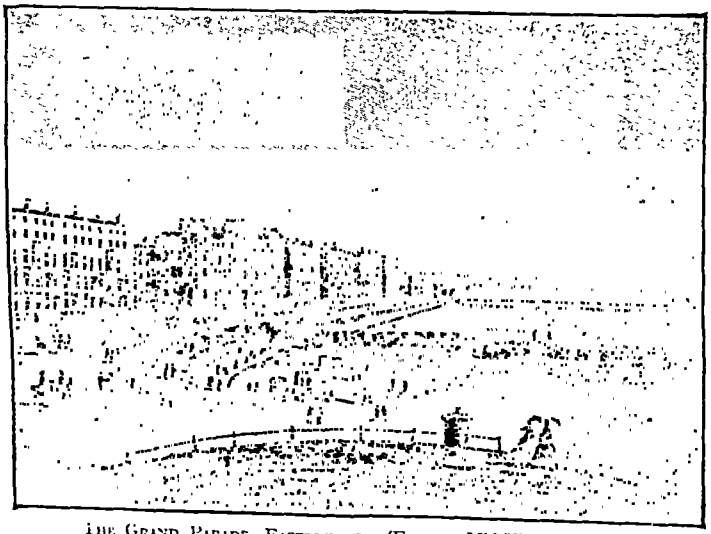
BEACHY HEAD

THE ninety-ninth Annual Meeting of the British Medical Association will be held at Eastbourne this summer under the presidency of Dr. W. G. Willoughby, medical officer of health for Eastbourne, who will deliver his address to the Association on the afternoon of Tuesday, July 21st. The sectional meetings for scientific and clinical work will be held, as usual, on the three following days, the morning sessions being given up to discussions and the reading of papers, and the afternoons to demonstrations. The Annual Representative Meeting, for the transaction of medico-political business, will begin on the previous Friday, July 17th. The provisional programme for the work of the fourteen Scientific Sections is being drawn up by an Arrangements Committee, consisting partly of Eastbourne representatives and partly of members appointed by the Council of the Association. The full list of presidents, vice-presidents, and honorary secretaries of the Sections, together with the provisional time-table, was published in the *Supplement* of March 7th. Other details of the arrangements for the Annual Meeting will appear in later issues. During the week, and in particular on the last day of the meeting (Saturday, July 25th), there will be excursions to neighbouring places of interest. We publish below the first of a series of illustrated articles dealing with the history of Eastbourne, and describing some noteworthy features of the town and its neighbourhood, with special reference to medical institutions.

EASTBOURNE IN HISTORY AND TO-DAY

The famous Sussex range of chalk hills, known as the South Downs, reaches its eastern extremity at Beachy Head, whose sheer cliff of 470 feet is the second highest in England. On the lower slopes of Beachy Head, the foothills of the Downs, and the beginning of the level country beyond, stands the town of Eastbourne.

As a town Eastbourne is new; as an inhabited part of the country it has a history pointing back at least as far as the Roman occupation. Extensive Roman remains have been found, including a tessellated pavement, coins, and a bath. Since it is known that the Roman town of Anderida was somewhere in the vicinity, it is possible that Eastbourne itself is on the site of it, but it is more likely that Anderida was where Pevensey now is, and that some person or persons of note—perhaps the commanding officer himself—chose to live on the pleasant sea coast west of the garrison town.



THE GRAND PARADE, EASTBOURNE. (From a Mid-Victorian print.)

The first written record is that contained in Domesday Book, where the town or village is referred to as Borne, and a brief note is given of its condition in the then ended Saxon times. Borne was always of sufficient importance to form a Hundred by itself, without the inclusion of other parishes. It had its own moot, whose existence is commemorated in the name of Motcombe, a farm (no longer extant as such, though the name still lingers) to the north of the Parish Church. The Hundred was divided into six districts; all six names are recorded, but only two are now used — Upperton, a residential district and a ward of the modern town, and Upwick, to the west of Upperton, whose name is recognized in Upwick Road.

The most ancient part of Eastbourne (leaving out of account pre-Norman civilization) is the part now known as Old Town, clustered about the Parish Church of St. Mary and the head of the Bourne stream, which gave the town its name. Here will be found many ancient buildings, foremost the church itself, and then the Lamb Inn, which is connected with the church by an underground passage. It is said to have been a custom for baptismal parties to use this passage to repair to the inn for refreshment after the ceremony.

St. Mary's was built in the twelfth century, in Transitional-Norman style, on the site of an earlier

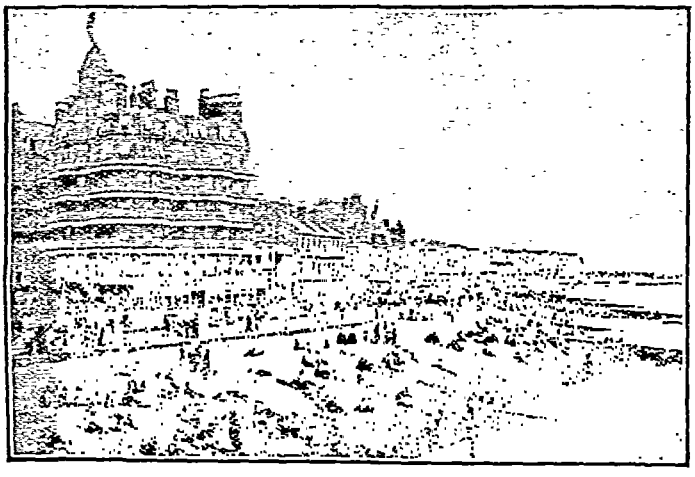
rch. As to this latter, there is a tradition that it a wooden church dating as far back as 680. However may be, the present building will be a delight to one interested in English churches. Naturally there e been additions and restorations at various periods n the fourteenth century onwards, but with little riment to the original building. St. Mary's has the racteristic squat tower, with low red-tiled pointed f, of the Sussex church. It will be noted that the e is set at an angle to the chancel, as in the cases of ne other ancient churches.

To the north of the church, down the hill, is the old rsonage, and below this again are Motcombe Gardens. ese gardens, though small and recently laid out, are ll worth a visit, for two reasons. The first is simply eir beauty; they are excellently kept, and the roses pecially are delightful. The second is that they contain source of the Bourne. The stream rises in Motcombe nd, now a formal ornamental water in the gardens, t until quite recent years a large irregular lake. It can seen issuing from the south-east corner of the pond, d passes thence under the road and the Star brewery; it then visible in Star Road, but after this it passes out sight for the rest of its course, at any rate as far as the iblic are concerned, ough it flows rough several ivate gardens.

At the corner of tar and Moat Croft oads is the old ourt House. The ourne is on the pposite side of Star oad; it flows under he very noticeable ip in the centre of loat Croft Road, nd then through ie gardens of houses a The Goffs. In the niddle of this reach vas one of the several nills which the Bourne was able to work before the municipal water schemes reduced the flow. It crosses The Goffs into Southfields Road (formerly Water Lane) at the beginning of the latter road. Here was another mill. After passing down the right-hand side of Southfields Road it flows (though still out of sight) behind the Technical Institute and Free Library. Within the memory of many living residents of the town there was a pond at this point. It then crosses under the busy centre of the town, and has been diverted into a part of the town's surface water system, but its original course may still be traced by the lie of the land, the lay-out of the streets, and even by the name of one of the streets—Bourne Street—along which it flowed to the point where it ran out into the sea through the shingle. This was near where Leaf Hall now stands—a fare stage on the bus route from the station to Archery or Langney. At this end of Bourne Street some cottages of obvious antiquity still stand, and the place is close to the old hamlet of Sea Houses. Some of the old Sea Houses can be seen on the front, a little east of the pier.

The main road from London enters Eastbourne just after passing through the village of Willingdon. A little way to the left at this point is the inland suburb of Hampden Park, brought within the town in 1911. The park itself was laid out in the earliest years of the present century upon the Decoy, a tract of wooded and watered country purchased from Mr. Freeman Thomas, now Lord Willingdon. Victoria Drive branches off the main road to the right, and passes through a populous district of post-war growth. The main road itself ascends a hill, the top of which is 215 feet above sea-level. From here a very fine view of nearly the whole town can be obtained. Down on the left is Rodmill Farm, several centuries old. Next, one enters Ocklynge; the name is now always pronounced so as to make the latter syllable rhyme with "hinge," but, as the spelling in an old map is "Ockling," it may be supposed that the soft "g" is new. Ocklynge was a chosen spot for windmills. Two still stand, now both without sails and one in ruins, though the other was in actual use until about the beginning of the war. On lower ground to the right is Old Town, from which The Goffs, passing the old Gildredge Manor House and Gildredge Park, joins the main road close by Upperton farm house, the last remaining building of old Upperton.

The main road continues as Upperton Road to the railway station, after which it becomes Terminus Road (the town's main thoroughfare), and later, as Victoria Place, meets the front. Just before the station, Grove Road branches off to the right, leads to the Town Hall, and then becomes Meads Road, leading to Meads Village (still spoken of as such) under the shadow of the Downs. The wider district of Meads embraces a large area with the village on its south-western edge, and includes the site of the now vanished hamlet of Prentice Street. Compton Place (the Eastbourne seat of the Dukes of Devonshire), the Royal Eastbourne Golf Club, and Paradise lie to the north-west.



ROYAL AND MARINE PARADES, EASTBOURNE

South Street, which begins opposite the Town Hall, is a very ancient thoroughfare, and is, in fact, said to be partly Roman. The buildings are now nearly all modern, but some old cottages remain, part-way down on the right. Before modern Eastbourne came into being, the area at the head of South Street constituted the village of South Bourne, which was, however, within East Bourne Hundred and Parish. These extended to the sea, and were not much smaller in area than the main part of the modern town.

Further down, Cornfield Road joins South Street with Terminus Road, and here were actual cornfields within living memory. These gave place to residences, which in turn are now giving way to shops, though some side roads remain purely residential. Cornfield Terrace, on the other side of South Street, leads to Devonshire Park, famous for the South of England lawn tennis tournament and many other attractions. On the left of Terminus Road is all the eastern part of the town, extending for about a couple of miles on level ground. At the extreme eastern end is Langney, both originally and now so spelt, though at an intermediate period the name was corrupted into "Langley," perhaps by false analogy with the many true Langleys which exist in the country.

The road passes through Langney to Pevensey Bay, and on its seaward side lie the Crumbles, an expanse of shingle several square miles in extent, the haunt of some rare species of birds. Langney Point is a tongue of the Crumbles stretching out into the sea and forming a dividing mark between the bay in which Eastbourne is situate and Pevensey Bay. There is an old brick fort on the point (much affected by coast erosion), one of the series of coastal defence works erected to meet the threatened invasion by Napoleon. More conspicuous are the Martello towers all along the seaward edge of the Crumbles, and extending even into Eastbourne itself; for the Wish Tower is one of these, and until recently another stood on an eminence at the eastern end of the town

(St. Anthony's Hill). The Martello towers, the Great Redoubt at the eastern end of Eastbourne front, and Langney Fort were all erected at the same period and for the same purpose. In the Wish Tower and the Redoubt, therefore, Eastbourne has a valuable reminder of one of the greatest crises in English history.

It will be seen from the foregoing that Eastbourne consists, in the main, of a valley leading to the sea and a sea front approximately at right angles to it. The town is thus roughly T-shaped, but the ridges to right and left of the valley are now covered with houses, and the cross-bar of the T has extended a very long way to the north-east, while being prevented by the natural obstacle of Beachy Head from extending far in the other direction.

The geographical situation of Eastbourne is ideal for a health resort, providing breezy heights in conjunction with proximity to the sea. The highest point in the county borough is 590 feet above sea-level. The sea front faces south-east and south; beyond Langney Point, Bexhill and Hastings can be seen in the distance.

The diversity of the surrounding scenery is remarkable, being different on all four sides; as one approaches the town, whether by road or by rail, there is the sea ahead, ordinary (though beautiful) country behind, lofty hills on the right, and a wide plain on the left.

Sunshine records are excellent. In 1929, not for the first time, Eastbourne headed the list of health resorts for the country, and in 1930 it secured second place. The subsoil is mostly chalk, but there is a strip of upper greensand, and clay appears over a small area in the centre of the town and also at Hampden Park, which is just beyond the end of the chalk. The eastern end of the town is on shingle.

One of the outstanding features of Eastbourne is the abundance of trees. This is no modern feature; in lining all the principal streets with trees the large estates have merely shown their good taste by perpetuating a tradition. References to Eastbourne over a century ago, when the town as a town did not exist, show that its thickly wooded character was one of its chief features. In view of these facts it is curious that one of the best-known species of British trees is conspicuous by its absence. This is the common deciduous oak. In Hampden Park it is abundant, and all over the town the evergreen oak finds no difficulty in growing, but in the main part of Eastbourne there is only one rather undersized specimen of the common oak, and that is sufficient of a phenomenon to have given names to two adjoining houses. The trees which line the streets are mostly elms, either ordinary or of the Cornish variety. The latter are somewhat preferred, since by reason of their conical shape they do not unduly darken the houses. Terminus Road has planes, reminiscent of London. There is at least one acacia in the centre of the town, and there are several horse-chestnuts; Compton Place and Paradise have fine beeches.

Eastbourne is situated in Lat. 50° 46′ N. and Long. 0° 17′ E. The Greenwich meridian passes through Lewes, the county town of Sussex, about sixteen miles by road from Eastbourne. The acreage of the county borough is 6,847, including 19 acres of inland water and 332 acres of foreshore. Much of its area consists of open spaces, in spite of the great and increasing population.

In 1859 the first local board was set up; in 1883 the town was incorporated, and in 1911 it was made a county borough, a distinction which among Sussex towns it shares with Brighton and Hastings. In 1926 the boundaries were further extended, and in 1929 a large area of the Downs was purchased for the town.

As one looks back at the population figures, one sees the rapidity of Eastbourne's increase in size. In 1801 the population was 1,668, in 1861 still under 6,000; in 1891 over 34,000, and in 1921 over 62,000. Much of the town's prosperity, and its fine terraced parades, are due to the foresight of successive Dukes of Devonshire. The construction of the sea wall has driven the fishermen east of the Redoubt, but Eastbourne was never primarily a fishing village, and this occupation has now for many years been less prominent locally than the letting of pleasure boats. Schemes for a harbour have been propounded from time to time, but not carried out. The continual eastward drift of shingle is a serious difficulty, and would indeed be a menace to the front itself were it not for the groynes.

It is fair, and by no means unduly flattering, to describe Eastbourne as a model of how a town should develop. It has increased enormously in a very short space of time, yet harmoniously always, and without ever acquiring the ugliness of uncontrolled expansion. The wise policy of the Duke's, the Gilbert, and other estates, and of the town's own authorities has borne, and is still bearing, a rich harvest.

Those who wish to go further into the history of Eastbourne are referred to *Bygone Eastbourne*, by Mr. J. C. Wright, published by Spottiswoode and Co., Ltd., to which, and to other works upon the subject, acknowledgements are due.

MEDICAL RESEARCH COUNCIL

ANNUAL REPORT, 1929-30

(*Concluded from page 413*)

THE NATIONAL SUPPLY OF INSULIN

Since 1922 the Medical Research Council has taken an active part in promoting the manufacture, availability, and clinical use of insulin in Great Britain, and a section in the report under review is devoted to a particularly important survey of some of the prevailing conditions of its administration. At first the supply fell short of the demand, but in 1923 the position was reversed, and since that time there has always been a sufficiency for the medical practitioners in this country, and a surplus for export. Early in 1930 the consumption of insulin in Great Britain was 50 per cent. greater than at the corresponding period in 1928, and nearly four times the figure for 1925. It is thus apparent that very many patients in 1925 needing this remedy were not receiving it; moreover, the present figures indicate that it is still being inadequately used, and this accounts for the disappointing slowness in the rise of its consumption since 1923. It is probable also that a large number of patients are not receiving insulin under proper conditions of biochemical control and dietetic balance, for there is a sharp discrepancy between the recorded success at all the chief medical institutions and the apparent steadiness of the death rate from diabetes for the country as a whole. This failure to diminish the death rate has been used as an argument against the value of insulin, despite the indisputable evidence of its life-saving properties, which is a matter of common knowledge to all practitioners. The death rate seems, in short, to demonstrate the failure of insulin, and yet there is ample clinical evidence to the contrary. This contradiction is examined critically in the report.

Since the war diabetes has apparently become commoner. Death certificates record the contributory as well as the immediate causes of the actual fatal termination, and the patient with an incurable disease is likely to be certified as dying from it, even if death is actually due to an intercurrent disease, or occurs at an advanced age. It is often forgotten, especially by prejudiced propagandists against such preparations as insulin, that it does not pretend to afford a cure, but only to prolong life, and to restore some considerable measure of health. Yet, even so, there should still be recorded some diminution in the deaths from diabetes at earlier ages; and this is actually the case, though not to the extent that might reasonably have been expected, had this preparation been used freely. In the Registrar-General's statistical review for England and Wales for 1928 it is stated that since the introduction of insulin

1923 the mortality of males with diabetes under the ge of 55 has been reduced by 37 per cent., and that of males by 21. The male rate for the period 25 to 45 as fallen by 45 per cent. But this fall is masked in the otal death rate by a concurrent increase in the mortality t ages over 55, which for males almost neutralizes, and or females outweighs, the reduction in earlier life. This ncrease, adds the Registrar-General, has evidently a ietetic origin, since the mortality at these more advanced ges was greatly reduced during the war, and has been ising again since 1918. It is pointed out, therefore, in he report of the Medical Research Council, that the nevitable conclusion is that the general use of insulin hroughout the country has been advancing only gradually, nd is still below the level of the maximum need. The ncreasing mortality among elderly diabetics, for whom nsulin treatment is less frequently used, indicates an bsolute increase in sufferers of this type ; moreover, the umber of deaths among the older patients must naturally ncrease with the extension of life among the younger ufferers from this complaint.

Such considerations are obviously of great practical mportance, and once again there is presented a tragic xample of the delay which occurs between the intro- luction of a new remedy and the time when the com- munity as a whole is educated sufficiently to reap the ull advantage of the discovery. The Medical Research Council has done well to direct attention to these facts ; it proposes to inquire during the present year into the results of insulin treatment at special centres, with a view to defining more precisely the standard of success attain- able under the best conditions, and so to measuring the results obtained for the country as a whole.

WORK AT HAMPSTEAD AND MILL HILL

Virus Infections

Captain Douglas and Dr. Wilson Smith have found that the blood and tissue cells of a normal animal possess a limited power of killing the vaccinia virus outside the body, a power due to a normal constituent of the serum which is easily destroyed by heat. The blood and tissue cells of an animal rendered immune to vaccinia were found to have acquired a greatly enhanced lethal activity towards the vaccinia virus. The washed tissue cells have, by themselves, an increased power of killing the virus, but it is clear that a specific antibody in the serum must contribute largely to the total effect. Dr. Wilson Smith has shown that each of the viruses of vaccinia and herpes absorbs from a mixture of the two corresponding anti- bodies its own specific antibody, leaving the other intact. Dr. Andrewes has been able to demonstrate that the union of the antibody of fowl plague with its antiserum becomes firmer with time, after being at first dissociable by dilution. At the ordinary room temperature some days may be required for this fixation—an interesting observation in view of the fact that immediate suscepti- bility to a virus may be conferred by injection of its specific antibody into a living animal. He has also found that the herpes virus is prevented from infecting normal cells when these are cultivated in the presence of an immune serum ; on the other hand, cells from an animal immunized to herpes are susceptible to infection by this virus if cultivated in normal serum. Dr. Wilson Smith has been able to confer on a definitely neuro- tropic strain of herpes virus the power of infecting the skin, and of producing reactions even in high dilutions.

Dr. P. P. Laidlaw and Mr. G. W. Dunkin have been investigating difficulties which have arisen in the practical immunization of dogs against distemper. After very successful results had been reported for some months it was discovered that in an increasing number of cases the expected immunity was not making its appearance. The processes of the preparation of both the virus and the vaccine were carefully scrutinized, and certain faulty details were brought to light and remedied. Preventive inoculation on a large scale will shortly be resumed, it is stated, with fuller knowledge and greater security. These two investigators have also been studying the complement-fixing antibody in the blood serum which confers immunity on a dog which has recovered from an infection with distemper or has been artificially im- munized. A possibility of standardizing the strength of both the virus and the vaccine seems to be now in sight, and also an improved method of preventive immunization which can be applied on a single occasion, obviating the need of repeating the injections.

Drs. Gye and Purdy have continued their work on the malignant tumours of birds and mammals, with special reference to the transmission of a myxosarcoma of the fowl by cell-free filtrates. The nature of immunity to certain types of tumour growth is being followed up, and in close co-operation with Dr. Andrewes it has been shown that the blood of a fowl which is offering good resistance to a slowly growing fibrosarcoma is particularly rich in antibodies which neutralize the infective property of filtrates from rapidly growing fowl tumours of quite different histological types. This evidence that the in- fective agents, producing fowl tumours of widely different types histologically, may be similar antigenically is highly suggestive.

Dr. Perdrau has been proceeding with his studies of a group of diseases of the brain and spinal cord which are characterized by the loss of the myelin sheath of nerve fibres. Although some of these conditions occur as a sequel to general infections by known viruses, such as the encephalitis which has followed vaccination in a small percentage of cases, Dr. Perdrau has in no instance been able to detect the virus in the nerve tissues. The hypothesis that the cause is a latent virus, which is awakened to activity by an acute infection, is being tested. Dr. Carmichael is investigating the possibility of the presence of a virus in the spinal fluids of patients suffering from disseminated sclerosis, and Mr. Galloway is co-operating with Dr. S. Nicolau of the Pasteur Institute in Paris on the conditions affecting the stability of the Borna virus of the enzootic encephalomyelitis of horses, cattle, and sheep.

Amoebic Dysentery.—Mr. Clifford Dobell, who has been studying the organism of amoebic dysentery at the Institute for six years, has been publishing at intervals his discoveries with regard to the varieties of *Entamoeba histolytica* met with in man and monkeys. He has been able by assiduous care to isolate any desired strain of this amoeba from a man or a monkey, and to maintain it in artificial culture for any period ; to obtain any stage in its life-history—for example, encystment—in the laboratory at any chosen time ; to introduce it naturally to a fresh simian host ; and to eradicate it at will by therapeutic means. Either the simian or the human strain can be shown to produce amoebic dysentery in kittens. Host and parasite can therefore be separated or united, and again separated, at will, and any desired experiment can be made with either or with both com- bined. No such power of control has yet been obtained with any other human or animal endoparasite.

Determination of Biological Standards.—The work of this kind now in progress includes the sterility testing of more than 100 varieties of catgut ; the standardization of vaccine lymph ; the assaying of a dried antiserum for the toxin of *B. welchii* and of antidysentery serum ; the estimation of strophanthus tinctures ; and the testing of the toxicity and potency of every batch of products of the arsenobenzine group made in this country.

WORK AT OTHER CENTRES

At the James Mackenzie Institute for Clinical Research, St. Andrews, Dr. A. Rowand is investigating 500 children in respect of their family history and environmental conditions, diet and general nutrition, dental disease, and sickness incidence. Records of 232 children are already complete, and are being analysed. A direct result of this inquiry has been the formation of a child welfare centre at St. Andrews, with special facilities for the continued observation of these children. Concentrated pneumococcal serum is being tried in pneumonia patients in London and Edinburgh; very favourable results have been reported from America following the use of this serum, but it is as yet too early to draw conclusions in Great Britain. At Sheffield Professor Mellanby and Dr. Roberts are studying the effects of carotene and vitamin A in pneumonia, rheumatic fever, and other infections. The part played by this vitamin in preventing the neurological changes in ergotism is also receiving attention, and an attempt is being made to discover the effective chemical factor in ergot. Dr. G. H. Oriel at Guy's Hospital, continuing his study of the allergic states, has obtained evidence that the "proteose" isolated from the urine in asthma and urticaria contains the specific antigen to which the patients are sensitized; encouraging clinical results have been obtained by desensitization. At St. Bartholomew's Hospital Dr. R. Hilton has made further observations on the effects of deep *x*-ray therapy on the lungs. Acute lesions are produced, but no appreciable fibrosis was discovered, even at the end of five months. If the lung has been previously collapsed by pneumothorax the effects of radiation are reduced.

The incidence of rheumatic heart disease is being investigated at Bristol by Dr. Carey Coombs, with special reference to the influence of soil and locality. The etiology of acute rheumatism is being studied by Dr. R. C. Lightwood in Kensington, and a rheumatic supervisory centre has been conducted at the Princess Louise Hospital for Children, where careful inquiry is being made into the possibly predisposing home and family conditions. The Council is assisting also an intensive search, now in progress at Great Ormond Street Hospital, into the etiology and treatment of rheumatic fever. At Guy's Hospital Dr. E. C. Warner is studying the nutritional history of children with rheumatic diseases. The vitamin food content of various Empire food substances is being determined at the Lister Institute, and a report has been published by the Council on the vitamin C content of apples. Dr. L. J. Harris, at the Dunn Nutritional Laboratory, Cambridge, has continued his work on the effects of overdosage with vitamin D, and in collaboration with Dr. A. N. Drury has made further studies of the relation of vitamin B deficiency to heart function. An inquiry into the changes in tooth structure produced by erosion, injury, and caries is being continued by Dr. E. W. Fish, and it has been found that the lymphatic tubules of the dentine, when injured, become isolated from the tooth pulp by a formation of "secondary dentine," and from the surrounding normal tubules by a local deposition of lime salts. Further studies of the response of dentine to injury have been made at the London Hospital by Mr. E. Sprawson, who has also been examining the changes in the lime salts of tooth enamel produced by injury and advancing age.

An exhaustive investigation of the common form of Raynaud's disease has been in progress at University College Hospital under the supervision and active direction of Sir Thomas Lewis. It has been shown now that the affected vessels are still capable of expanding fully, or almost fully, under suitable conditions, and that the veins do not ordinarily become closed in spasm. The arteries behave abnormally when there are changes in the local temperature, this being a direct reaction, due to a peculiar condition of the vessel wall and not to a vasomotor nervous reflex. The state of the vasomotor nerves naturally influences the tone of the vessels in these patients, as it does in normal people, but the pathological element in the vascular spasm is not of nervous origin. Another mechanism, demonstrated in this connexion, is the vaso-dilatation in the skin of the finger after it has been immersed in cold water for five to ten minutes. This reaction has also been obtained in the ears and other parts of the face. It is independent of the sympathetic nerves, but is dependent upon the sensory nerves, and due to an axon reflex in them. This mechanism, which is brought into frequent play during cold weather, has an important function in protecting exposed parts of the skin from excessive cooling and resulting injury. Sir Thomas Lewis has also compiled the results of many years of observation of cardiac failure of the congestive type, with a view to showing how the stages of this malady may be recognized by simple bedside tests.

STATUS LYMPHATICUS

INVESTIGATION COMMITTEE'S REPORT

In January, 1926, the Medical Research Council and the Pathological Society of Great Britain and Ireland jointly formed a committee for the investigation of "status lymphaticus," and for the collection of information on a large scale on the weights and measurements of the thymus gland. An earlier inquiry, organized by the late Professor Emrys-Roberts, resulted in the accumulation of a certain amount of material and the publication of an interim report,[1] but the number of records was too small to permit of the deduction of any authoritative conclusions. The present scheme was initiated in an endeavour to collect a much larger mass of material.

The special objects of the investigation were primarily: (1) to establish by means of a large series of weights and measurements the standards of weight for age and proportion to body weight of the normal thymus at all ages; and (2) to investigate closely the precise cause of death in persons dying suddenly from unexplained or trivial causes where the only apparent abnormality was the presence of a large thymus. A number of investigators were appointed in certain large centres of population, and special record cards were issued. The cases in which information was specially desired were divided into two categories: (*a*) cases of sudden death in apparently healthy persons of any age, and (*b*) cases of death in persons of 15 years or over who had an apparently glandular thymus. After the inquiry had been in progress for some time, coroners began to cease ordering necropsies in ordinary street accident cases, with the result that there was a great reduction in the amount of available material. At the termination of the inquiry a total of 710 record cards had been collected by the secretary of the committee, Dr. Howel Evans. Of these, 30 had to be discarded on account of their giving insufficient information, leaving 680 available for analysis.

A preliminary pathological scrutiny and classification of the available material was undertaken by Professor H. M. Turnbull of the London Hospital, and the final statistical analysis by Dr. Matthew Young of the Medical Research Council, both of whom were members of the "Status Lymphaticus" Committee. Their report appears in the current issue of the *Journal of Pathology and Bacteriology*.[2] The value of the results obtained is

[1] *Journ. Path. and Bact.*, 1925, xxviii, 132.
[2] Ibid., 1931, xxxiv, 213.

enhanced by comparison at every stage with the figures of Hammar, Bratton, and Greenwood and Woods.

The conclusions of the authors (the actual figures are given in a series of fifteen tables) may be summarized as follows:

The average weights of the normal thymus shown for the several ages from 1 year upwards and the mean percentage proportions of thymic weight to body weight may be considered to be well established within narrow limits as they are in close agreement with those of other recent observers. The mean absolute weight of the thymus and the mean ratio of thymic weight to body weight at ages 0 to 1 year sensibly exceed the corresponding values based on data published by Greenwood and Woods and by Bratton from the London Hospital, but the data are not numerically adequate to warrant any emphasis being laid on the differences observed.

There is no evidence in the relatively few data available that acute diseases of short duration—that is, under three days—reduce the average weight of the thymus to an appreciable degree.

An abnormally large thymus *in itself* cannot be considered to be indicative of " status thymico-lymphaticus " when no obvious cause of death is found post mortem. In the series of *normal* cases under investigation a thymus which may be considered abnormally large for the age was found in twenty subjects, ten of whom were under and ten over 16 years of age, but of this number in only four, in which the death was attributed to anaesthesia or shock, can any special liability to death be assumed to have possibly existed or the cause of death be regarded as possibly inadequately explained. It is impossible to judge the adequacy of anaesthetics or shock as causes of death because their effects cannot be measured in the dead body. The cases in which death was attributed to anaesthetics or shock are therefore most important, and have been given in detail. There were twenty-three such cases. Of the four in which the thymus can be considered to be abnormally large for the age ; in one a major operation had been performed, in one purulent bronchitis, dilatation of the right ventricle and hypertrophy of the left ventricle were noted at necropsy ; in the other two the conditions were apparently similar to those in other cases in which the thymus was not unusually large.

In the normal series of cases at ages 0 to 16 years there appears to be little if any association between the weight of the thymus and the amount of lymphoid tissue in the various parts of the body, in so far as this amount can be indicated by volumetric measurements of the faucial and lingual tonsils, selected lymph glands from certain sites, Peyer's patches, etc. There is no definite evidence in the relatively few data available of any concomitant general hyperplasia of lymphoid structures in cases with an abnormally large thymus. The amounts of lymphoid tissue in the several parts of the body, in so far as they can be considered to be represented by the selected criteria, seem to show practically no association with one another to which any significance can be attached.

In a series of subjects with Graves's disease, there is evidence that the average gross weight of the thymus is distinctly above the normal, thus providing confirmation of what is more or less general opinion based on naked-eye observation that the thymus almost invariably appears to be abnormally large in this affection. Though the relatively few data available do not warrant any definite conclusions they suggest strongly that the percentage proportion of glandular tissue in the thymus is above normal, but that there is no definite general hyperplasia of lymphoid structures in this affection.

There is no evidence, in the series examined, of an association between arterial hypoplasia and an abnormally large thymus.

In the opinion of the committee the facts elicited in the present inquiry are in harmony with those of Hammar and Greenwood and Woods in affording no evidence that so-called "status thymico-lymphaticus" has any existence as a pathological entity.

England and Wales

Medical Society of London

The 158th anniversary dinner of the Medical Society of London was held on March 6th at the Trocadero Restaurant, with the president, Dr. R. A. Young, in the chair. The guests at the high table included Sir John Rose Bradford, Bt., President of the Royal College of Physicians, Surgeon Vice-Admiral Sir Arthur Gaskell, Medical Director-General, R.N., Lieut.-General Sir H. B. Fawcus, *D.G.A.M.S., Lieut.-Colonel C. T. Samman*, Master of the Society of Apothecaries, Dr. T. Watts Eden, President of the Royal Society of Medicine, and the presidents of other kindred societies, Dr. H. B. Brackenbury, Chairman of Council of the British Medical Association, Sir Thomas Horder, Bt., and Sir William Rothenstein (who delivered the Lloyd Roberts Lecture in the Society's House last autumn). After the loyal toasts had been honoured, Mr. Norman Birkett, K.C., M.P., proposed prosperity to the Medical Society of London. Remarking that extempore speeches were " seldom worth the paper they were written on," Mr. Birkett said he had conferred with his junior on analogies and contrasts between medicine and the law, and was told that the dominant thought in the lawyer's mind when finishing a case was, " Have we left anything *out*?" The impression he had formed of the Society, after reading its rules, with their kind and considerate tone, and their air of hospitality and good-fellowship, was amply confirmed by dining with the Fellows. The President, in responding to the toast, remarked that while lawyers and doctors had this in common—that they both saw human nature in difficulties—he envied lawyers for the crispness of their medical knowledge and its tidy arrangement in compartments. He was proud to be the head of the oldest public medical society in London, one which attracted in a peculiar degree the esteem and affection of all its Fellows. Quoting from Sir Thomas Browne, " 'Tis opportune to look back upon old times and contemplate our Forefathers," Dr. Young said that the spirit of Lettsom still seemed to brood over the Society ; through all its proceedings a gentle friendliness prevailed. It now owned its own house, its finances were satisfactory, and steps were being taken to raise an endowment fund. Its debt to the honorary officers and the registrar was great, and it owed much, also, to the two medical journals. The health of the visitors was proposed by Lord Dawson of Penn, who said that to do justice to so many distinguished persons could only be attempted in the spirit of the two American girls who " did " Westminster Abbey in ten minutes and then aggregated their observations. He welcomed the editors of the *Lancet* and *British Medical Journal*, and paid compliments to both papers for their strength and independence, their comprehensiveness, and their unity in diversity. Speaking of Mr. Birkett, Lord Dawson said that in the nature of things lawyers always differed, and if doctors also occasionally disagreed it was out of differences of opinion that progress grew. Unlike journalists, but like the practising doctor, the lawyer could not afford to make mistakes. Among the other guests

whom they had the pleasure of greeting that night, Sir William Rothenstein appealed in a special degree to doctors, because he was both artist and teacher. Their President, too, was an artist in his profession and a lover of the arts. Lord Dawson coupled the toast with the name of Mr. E. R. Peacock, whom he described as "the man who does things."

The Trend of Medical Practice

At the last meeting of the London Jewish Hospital Medical Society, Mr. Somerville Hastings, M.P., delivered an address on "The trend of medical practice." In this he pointed out the tendency in modern medicine to take many branches of practice out of the hands of the family doctor and concentrate them in some form of State organization—for example, preventive medicine and public health, infectious diseases, lunacy, venereal disease, tuberculosis, and maternal and child welfare. The exigencies of research were demanding further centralization in the campaigns against cancer and rheumatism and maternal mortality, and in the grouping of orthopaedic cases. This process was bound to continue, partly because it tended to greater efficiency and had contributed much to the improvement in the general standard of physical well-being; and partly because the spirit of the age demanded collective action in meeting its needs. It was being recognized that the team and not the individual was the true unit in medical practice, a principle exemplified in the work of the modern general hospital. The general practitioner should act as a liaison officer, maintaining contact with his patient throughout his treatment and co-ordinating the work of the team. He should have his definite place in the hospital system, and, in fact, an ideal scheme demanded the institution of district clinics as the places of first resort, rather than the private surgery or the out-patient department of a hospital. The inability of the voluntary hospitals to provide the necessary accommodation would throw more and more work upon the new council hospitals, which must eventually rival the voluntary hospitals in the quality of their work, by reason both of greater financial backing and greater resources of material for practice, teaching, and research. Mr. Hastings advocated the inclusion of dependants in the National Insurance scheme, but would extend it to all classes irrespective of income, and make it non-contributory, thus providing a free national medical service, complete with specialist service, and opening all the resources of medicine equally to all. The cost must be borne by State funds, so that the burden would be distributed in accordance with the age-long principle of medical practice—namely, "from each according to his means." Mr. Hastings was of the opinion that the increasing demand among the public for a form of State medical service must result in the setting up of some such system; and it behoved the medical profession to anticipate this, and ensure the creation of a fair and efficient scheme by close and sympathetic attention to the problem.

Central Council for District Nursing

The annual meeting of the Central Council for District Nursing in London, under the chairmanship of Sir William Collins, was held at the County Hall on February 26th. The annual report, which was presented to the meeting, stated that the past year had been eventful for those concerned in district nursing owing to the changes brought about by the Local Government Act, 1929, also by the expansion and reorganization of services required in the growing "dormitory" districts of London, and extension in districts of Middlesex, hitherto rural, which are becoming considerable towns. In the main the old-established associations of district nursing in London adhere to their system of voluntary subscriptions and donations, but the new associations, owing to changed economic conditions, are formed oftener on a provident basis, and the difficulty of a provident system lies in creating and sustaining local interest. The finances of the council, which is charged with the duty of systematizing arrangements for district nursing throughout the metropolitan area and promoting the adequacy and efficiency of such nursing, are at present very much diminished, and its activities are hampered thereby. The donations received during the year, principally from the trustees of the London parochial charities, amounted to £4,836; this sum includes £533 voted by the London County Council for midwifery and maternity nursing. A sum of £4,553 was distributed to the district nursing associations, and small sums by way of grants were paid for midwifery bursaries and for extension of nursing services. It is stated to be increasingly difficult to tap fresh sources of income, and King Edward's Hospital Fund does not see its way to give further help. One matter reported was that a number of members of the Hospital Saving Association are under the mistaken impression that as members of that association they are entitled to free district nursing. The awards of the Hospital Saving Association go entirely to hospitals, and the association does not think it feasible to include district nursing within the purview of its scheme. It is proposed that the executive committee of the Central Council should conduct an inquiry as to the adequacy and efficiency of the provision of district nursing within the county of London, making such recommendations as may be desirable for systematizing and improving the arrangements; also that it should report on the extension of the work of the Central Council beyond the area of the county of London. The representatives of the British Medical Association on the council are Dr. William Paterson and Dr. David Roxburgh. The former is a member of the executive.

Sunderland Royal Infirmary Pathological Block

A new pathological block, which has been provided at a cost of £7,000, was opened at the Sunderland Royal Infirmary by Lord Dawson of Penn on February 7th. Mr. Samuel Storey, chairman of the Infirmary, said that the block was one of the schemes of reconstruction of the Infirmary organized with a view to extending its service and developing its site to full capacity. The institution was ready to co-operate with the other voluntary hospitals of the district and also with the municipal hospitals in the provision of thoroughly up-to-date facilities, but he felt that it could best take its part in such a system by first making itself as efficient as possible. The first step in the scheme had been the provision of new wards, known as the Princess Mary's block; the erection of a new administrative block was now going forward, and when this was completed it would be possible to add another block of wards, increasing the capacity of the hospital by 80 or 90 beds. It had largely been due to the work given to the hospital by the local authority and by other hospitals of County Durham that the pathological department had been established; those responsible had felt justified in going ahead and putting up new laboratories of the most modern type. Lord Dawson then spoke of the courage of a community, in a time of almost unexampled depression, in taking upon itself such a piece of work as this. The new block would represent in a special sense the power of knowledge. The sciences of pathology, biochemistry, and bacteriology would be applied, and here physicians, surgeons, and pathologists would discuss their common problems. In passing, he mentioned the prejudice which still existed against post-mortem examinations. If a person consented, while alive, to surgical operations, why

should we object if equally skilful and reverent operation were performed after death? Often vital knowledge had been lost because it had not been possible to complete an investigation in that way. He complimented the institution on making good provision for post-mortem investigation of such cases as were likely to benefit the cause of knowledge. Lord Dawson also spoke of the hospital problem in general, and of the need for co-ordination among groups, in which respect Sunderland and the county of Durham were well to the fore. The Bishop of Durham proposed, and Sir John Priestman, chairman of the Monkwearmouth and Southwick Hospital, seconded, a vote of thanks to Lord Dawson, who then opened the new department with a golden key.

Scotland

Scottish Scientific Advisory Committee

The Secretary of State for Scotland has appointed Professor *D. P. D. Wilkie of Edinburgh to be a member* of the Scientific Advisory Committee on Medical Administration and Investigation. This committee was constituted a year ago to advise the Department of Health for Scotland on the application of the results of scientific research to public health administration, and to promote medical investigations under the Department of Health and the Scottish local authorities.

Presentation to Dr. W. T. Barrie

Dr. William Turnbull Barrie has been presented with a public testimonial on completion of fifty years of practice in Hawick. Dr. Barrie graduated at Edinburgh in 1880, and has been one of the best-known practitioners in Hawick district since that time. The sum subscribed was 1,000 guineas, and in making the presentation the executive committee handed to Dr. Barrie an illuminated address. In acknowledging the gift Dr. Barrie said his ambition had been to deserve the confidence of his patients and fellow citizens, and this presentation indicated that he had succeeded better than he knew.

Edinburgh Social Union

Progress in public health administration during the last half-century, especially in regard to housing and sanitary conditions, is referred to in the annual report of the Edinburgh Social Union for the year ended November, 1930. Forty-six years ago, when the union was founded, the powers conferred by the Public Health Act of 1867 were only beginning to be enforced. Organized interest in slum property was negligible, and heavy rents were charged for filthy and dilapidated rooms. In London the evils of degraded surroundings were early recognized by Miss Octavia Hill, who assumed the duties of a slum landlord by purchasing the fifty-six years' lease of three houses in one of the poorest courts in Marylebone. *Her success was remarkable*, and the system she devised, based on regular repairs and personal supervision, was adopted by the union in Edinburgh on its establishment. Since then the administration of the Public Health Acts through the co-operation of medical officers of health and chief sanitary inspectors has become an integral part of local government. At present the work of the union is confined to maintaining a standard of comfort in old houses until new accommodation is available; but efforts are hampered, and apparently often frustrated, by acute conditions of overcrowding. While the Edinburgh Corporation has built a number of new houses suitable for the small wage-earner, it is obliged by various Housing Acts to provide accommodation, first, for persons whose houses have been condemned in slum areas, and secondly, for the homeless—those living in lodgings, unfurnished houses, or with relatives. Hence it has been found impossible to relieve congestion by removing large families to more spacious dwellings. The report mentions, however, that there is a prospect of a steady supply of new houses for which families living in overcrowded conditions will be eligible tenants. Some concluding remarks emphasize the need for extreme care in slum management and direct attention to the outstanding difficulties that have retarded achievement since the end of the war.

Edinburgh Foot Clinic

At the annual meeting of the Edinburgh Foot Clinic, held on March 5th, Viscount Novar, who presided, referred to the importance of the work that had been done by Mr. and Mrs. Norrie, the founders of the clinic. Skilled attention of the highest kind, he said, was always available for major operations and for the treatment of fashionable complaints like appendicitis, but comparatively little provision had been made for the treatment of minor ailments of the feet. Were it not for the cheap, voluntary, and efficiently organized service provided by the Edinburgh Clinic, thousands of men and women would continue to suffer from foot infirmities. He intimated that Her Majesty the Queen had taken a great interest in the work of the clinic, and had given contributions to it on several occasions.

Correspondence

MORTALITY IN ACUTE APPENDICULAR DISEASE

SIR,—I am most gratified to find from the letters in the *Journal*, and from many which have come to me directly, that acute obstruction of the appendix is now widely recognized as a pathological and clinical entity.

Mr. Rayner and Mr. Blair question my conclusions on the subject of mortality. Possibly I did not make my position quite clear. I should not suggest that of all the cases diagnosed as acute appendicular disease the percentage mortality is higher now than twenty years ago. What we cannot get away from, however, is the fact that in this island there are more than three thousand deaths every year from this disease. I maintain that over three-fourths of these deaths occur in cases of the obstructive type. The tens of thousands of operations for acute appendicitis performed annually in this country have not reduced this absolute figure of three thousand odd deaths. Why? Either early operation is not a life-saving measure or the fatal type of case is not being operated on sufficiently early. The first answer is manifestly absurd; the second is, I believe, the true explanation.

The majority of the present-day operations for acute appendicitis are "luxury" operations in the sense that, whilst desirable as a safeguard against possible immediate and future trouble, they are not really life-saving. The cry for early operation has brought into our hospital figures more and more cases of the early inflammatory type of the disease which does not threaten life. Consequently our percentage recovery rate improves and flatters our surgical skill.

I do not for a moment condemn early operation in this type of case, but I do maintain that we must make a resolute effort on the "three thousand." This can be done if, in our teaching of medical students, nurses,

health visitors, and child welfare workers, we concentrate on the grave significance of severe afebrile epigastric colic associated with vomiting and the immediate necessity for a surgical opinion when such symptoms are met with.—I am, etc.,

Edinburgh, March 2nd. D. P. D. WILKIE.

THE INCISION FOR APPENDICECTOMY

SIR,—Mr. A. H. Southam, in his interesting article on the incision for appendicectomy (*Journal*, February 14th, p. 258), confines himself to a consideration of three incisions—the McBurney gridiron incision, Battle's incision, and the paramedian incision. When the diagnosis is in doubt, or when a general exploration of the abdominal cavity is required, it is agreed that the last incision is to be preferred. In cases of frank appendicitis there is considerable divergence of opinion among surgeons as to the best incision to be used. In addition to the incisions mentioned above there are at least two others to be considered. Some surgeons prefer to make a blunt dissection incision through the middle of the rectus muscle, retracting any nerves encountered up or down as may be convenient. I learnt this incision and used it for a time, but abandoned it as I was not satisfied that the part of the muscle central to the incision retained its innervation unimpaired.

The incision to which I would particularly draw attention is the transverse incision of G. G. Davis of Pennsylvania. For the past few years I have used this incision as a routine in children and in thin adults. The method gives extremely good access to the caecal area, and has the added advantage that if drainage is required the drain can be brought out right up against the anterior superior spine, where the risk of subsequent hernia is very slight. The skin incision extends from the mid-line to the anterior superior spine. Rather more superficial vessels are encountered than in the gridiron incision. It has been stated that the skin below the incision is apt to become oedematous, but this objection is in my experience entirely unfounded. The aponeurosis of the external oblique is now incised in the line of the skin incision. The method of splitting the aponeurosis is a matter of some anatomical importance. If it is desired not to open the rectus sheath the aponeurosis is incised at the outer end and the incision prolonged inwards with blunt-ended scissors. This is not advisable in small children, as it hardly gives a sufficient exposure. The incision is therefore commenced at the inner end, and the rectus muscle at once exposed by incising both layers of its anterior sheath. These layers are quite distinct, and the anterior layer, which is really the aponeurosis of the external oblique, is then picked up and divided for the full length of the skin incision. The deep layer of the anterior sheath of the rectus is then divided outwards as far as the edge of the internal oblique, the muscle fibres of which are separated by blunt dissection in the same line. At a deeper level the fibres of the transversus abdominis are separated in a similar manner. By sweeping the muscle fibres apart with two fingers a wide area of transversalis fascia is exposed. The peritoneum is opened in the line of the incision, and the caecum is at once exposed. In closing the abdomen a single Z suture brings the deep muscles lightly together. A second suture then picks up both layers of the anterior rectus sheath. At the margin of the sheath the suture is continued in the anterior layer or aponeurosis of the external oblique.

The fact that the aponeurosis of the external oblique is divided in a line which crosses the direction of most of the fibres does not appear to be any disadvantage. Tendinous fibres almost always unite soundly, and it is possible that the resulting scar is firmer than that of the gridiron incision, where the fibres are separated in the direction of their length; at any rate I have not encountered any subsequent hernia or even weakness after this incision. The skin incision lies along the line of the abdominal creases, and is inconspicuous.—I am, etc.,

London, N.8, March 3rd. A. ERNEST SAWDAY.

BACKACHE IN WOMEN

SIR,—The article upon the above subject in the *Journal* of February 28th calls for some comment on account of the incorrectness of its physics, as well as on account of its omissions.

In the first place it is a well-known law that pressure exerted by fluids, such as air or liquids, is equal in all directions, and therefore the projection of the upper portion of the sacrum into the pelvic canal can have no appreciable influence in protecting the pelvic viscera from the general intra-abdominal pressure. If anyone doubts the truth of this statement a very simple experiment with a couple of pressure gauges will prove its accuracy.

With regard to the occurrence of the true backache which follows exertion (more especially that which involves stooping) a careful study of the spinous processes of the vertebrae will in many cases show that there is deficient mobility of certain vertebrae or groups of vertebrae, and that they do not take their normal part in the movements of flexion and extension of the spinal column. Such fixation of vertebrae is most frequently due to persistent habit-spasm of the short muscles. The spasm can be overcome by relaxing movements such as those which are commonly used by the osteopaths, or, if not too habitual, it may be relieved by rapid, rhythmical, rotating movements of the body when sitting erect, which can be practised by the patient. In cases where there is no vertebral disease (such as that which may occur in rheumatoid arthritis) this treatment will usually suffice to restore the mobility of the intervertebral joints and completely cure the patient's backache.

A far commoner cause of backache is, however, one which may follow simple weariness, quite apart from stooping, and may also be troublesome and prevent sleep at night. This pain will be located in the region of one or both sacro-iliac joints. It is not of spinal origin, but is a referred pain, and the area concerned is that which is in relationship with the twelfth dorsal segment of the cord. Adequate irritation of any abdominal organ which is in relationship with the twelfth segment of the cord may originate such a pain. The commonest source of such pain is the colon. In cases where the colon is hardened and tender on palpation, a sudden sharp pressure upon it (in either the left or the right iliac fossa) may elicit this type of back pain. Such patients are, as a rule, speedily relieved by treatment of the colon ailment with an intestinal antiseptic and 20 minims of tincture of hyoscyamus, combined with the careful elimination from the diet of the type of cellulose-containing vegetable material which is normally digested in the colon.

There are also other omissions, such as the backache due to a prolapsed left ovary being compressed behind a uterus which is slightly prolapsed and retroverted, and the backache due to a dropped kidney. Very many of the cases of persistent backache which are met with in practice will, however, be found to fall into one or other of the two classes above described.—I am, etc.,

Birmingham, March 3rd. T. STACEY WILSON.

X-RAY THERAPY IN CANCER OF THE LUNG

SIR,—In response to Dr. Chalmers's request for results obtained in other centres in the treatment of malignant disease of the lungs by *x* rays, I append notes of cases of this type treated by me during the years 1928-30. I have not gone back further than 1928, as none of the patients whom I have treated during the last ten years have survived more than three years from the beginning of treatment. My results, however, do not appear to be so disappointing as those given by Dr. Chalmers and Mr. Tudor Edwards. Out of a total of twenty-four cases of primary carcinoma of the lung, twelve patients showed no response to treatment, and died within three months; of the remaining twelve, all showed improvement in general health, and gave evidence either of regression or of arrest of the spread of the disease. Six of these patients survived for six months, four survived for over one year, and two for just over two years.

The response in secondary lesions was much better. Twenty of these cases were treated during the same period, and fourteen of the patients reacted favourably to *x* rays; all were practically free from symptoms nine months later, eight survived for twelve months, five for two years, and three are still alive to-day. In all these cases improvement in clinical signs corresponded with disappearance of the radiographic features of the disease. It would appear, therefore, that *x*-ray therapy in pulmonary invasion does afford some measure of control, and it is certainly deserving of wider trial and of further investigation. As administered at present it causes but little discomfort to the patient, and it is attended with comparatively trifling risk.—I am, etc.,

Leeds, March 6th. G. COOPER.

THALLIUM AND ITS RISKS

SIR,—I think I have read all the articles published in the *British Medical Journal* during the past four years on the subject of the treatment of ringworm of the scalp by thallium acetate; but I have not noticed any mention of the added risk in giving a second dose. The only serious toxic results I have seen have been in cases where a second dose had been given on account of the failure of a single dose to secure efficient epilation. The following is an example.

A female, aged 5, received her first dose of thallium acetate on August 26th, 1927. Inefficient depilation followed, leaving many infected stumps. A second dose was given on October 24th. On November 7th the child was admitted to hospital suffering from severe collapse and repeated vomiting. By November 9th the vomiting had ceased, but there was marked mental aberration, drowsiness, and irritability. Next day she was better. The legs remained very stiff for some two or three weeks. There were no toxic symptoms following the first dose.

The child's sister, aged 6, also had two doses, without any toxic signs. I may say that I personally examined and weighed the children, and also dispensed the drug in all cases. Other patients to whom a second dose was given had less severe toxaemia.—I am, etc.,

JAMES A. MILNE, M.D., D.P.H.,
Joint Medical Officer to Dr. Barnardo's Homes.

Woodford Bridge, Essex, March 4th.

SIR,—I should like to add my testimony in favour of the treatment of ringworm of the scalp with thallium acetate to that of Dr. Gardiner and Dr. Hector Percival in your issue of February 28th.

I have records of thirty-two cases treated in my out-patient department at the Royal Alexandra Hospital for Children, Brighton, since 1927. Of these, thirty-one were cured, and one discontinued treatment. One of those cured exhibited serious toxic symptoms, which were reported by Dr. M. C. Andrews and myself in the *British Medical Journal* of December 17th, 1927. This was a patient 9 years of age, weighing 65 lb., who received a dose of 8.5 mg. per kilo of body weight. All the rest had 8.75 mg. per kilo; no symptoms beyond slight transient pains in the knee-joints were observed. Of these, four were over 8 years of age, and averaged 56 lb. The youngest child treated was aged 3, and the average age was 5½ years. The longest time taken to achieve cure was 20 weeks, the shortest 4 weeks, and the average 8.3 weeks, reckoning from administration of the thallium to final discharge of the patient with leave to return to school, etc.

While every effort is made to obtain *x*-ray treatment for those children who are entitled to it from the school authorities, I myself shall continue to use thallium with the greatest confidence. Five years' experience of it has convinced me that its after-treatment is only slightly more difficult and troublesome than that of *x* rays. It would be a great pity if this really valuable method of treatment were to fall into undeserved disrepute merely because somebody once made an error of over 500 per cent. in dispensing the drug—well known to be poisonous.—I am, etc.,

Hove, March 5th. J. H. TWISTON DAVIES.

THE ELECTROCARDIOGRAM

SIR,—I venture to suggest that your leading article on the electrocardiogram in to-day's issue misrepresents the significance of Dr. Craib's work, and it is extremely doubtful whether Dr. Craib himself would be ready to defend the sweeping conclusions which are based upon it. The value of his work, which has always been of the highest order, lies in its contribution to the academic and physiological side, and it cannot close the door to the importance of further clinical electrocardiographic study. Just as academic pharmacology can frequently find no sound basis for the known clinical effects of many drugs, so electrocardiograms of the diseased human heart may be difficult to read even in the light of the most careful experimental physiological work.

It is implied in your leader that "the electrical record of a regularly beating heart" is of no value whatever. Yet an electrocardiogram in a case of A-V heart-block or of branch-bundle block, to mention only two examples, may be of the utmost value in diagnosis, prognosis, and treatment; and in each case the pulse may be regular and normal in rate.

The conclusions of the last paragraph need to be qualified. That myocardial infarction can occur under certain circumstances without affecting the galvanometer is well known; yet in clinical work it is not unusual in suspicious cases to use leads in a plane transecting the plane of the ordinary leads. Without questioning the accuracy of the second conclusion, a low voltage in all leads is of serious import in many cases of heart disease, though the converse is not true. And the final sentence, though it may be correct as it stands, conveys a far more sweeping implication than the nature of the work done has justified. Without being unduly "vociferous" or "enthusiastic" I am not alone in the belief that correlation of clinical features with electrocardiograms, if possible periodically repeated, is becoming increasingly important in cases of chronic myocardial disease.—I am, etc.,

C. BLANLAND LEVICK.

Cardiographic Department, St. George's Hospital, March 7th.

DIVERTICULA OF THE DUODENUM

SIR,—The article by Dr. S. Gilbert Scott in the *Journal* of February 28th raises the interesting point as to the symptomatology of this condition. About a year ago I saw a man, aged 60, who for some weeks had had vague central abdominal pain soon after food associated with obstinate constipation ; he had never previously suffered in this way. Physical examination failed to reveal anything abnormal, and so he was put on a suitable diet and treated on general lines for a week or so to watch progress. The lack of improvement under this regime suggested the possibility of malignant disease of the bowel, and a complete *x*-ray investigation was instituted, with the result that there was found to be hyperactivity of the stomach and also a small diverticulum 1 inch long at the end of the first part of the duodenum. With this knowledge the patient was given further instructions as to the importance of diet and was treated with alkalis, so that at the end of two months his symptoms had disappeared, and he had put on nearly a stone in weight; since then he has been quite well, though the question still remains whether the diverticulum *per se* was the cause of the trouble.—I am, etc.,

W. R. THROWER, M.B., M.R.C.P.

Weymouth, March 4th.

ROUTINE ANAESTHESIA IN MIDWIFERY

SIR,—In the article entitled " Routine anaesthesia in midwifery " in your issue of February 28th it is suggested that there is some doubt as to the number of patients who would accept anaesthesia if offered it. This doubt can, I think, be entirely resolved by the study of the figures of anaesthetics given in Queen Charlotte's Hospital, where the policy of giving light anaesthesia to as many cases as possible has been adopted since May, 1928. I enclose the report of the resident anaesthetists for January, 1931, which shows that out of 127 patients only one refused anaesthesia. In previous months there have frequently been no such refusals, and never more than two, making an average of less than 1 per cent. It thus appears that there is no foundation for the belief that patients object to anaesthesia during labour; on the contrary, it is most ardently desired.—I am, etc.,

J. E. WILLIAMS,
Honorary Treasurer, Queen Charlotte's Hospital Anaesthetic Fund.

March 6th.

DISSEMINATED SCLEROSIS RESEARCH

SIR,—In your issue of March 7th there is a joint letter from Dr. Braxton Hicks and Dr. Hocking, who, among other statements, make the following: that Miss Chevassut's recent refusal to demonstrate a spherule in disseminated sclerosis under her own conditions in another London laboratory has led Sir James Purves-Stewart to dissociate himself from further collaboration with her. There are also references to Miss Chevassut's " negative findings," and a further statement that Dr. Hicks and Dr. Hocking are unable to confirm many of her results. In order to place the position in its true perspective, and also in fairness to Miss Chevassut, I venture to call your attention to the following facts.

1. Miss Chevassut cannot be responsible for the inability of any persons to confirm her findings, in the particular technique involved, who have not been trained under the guidance of Mr. J. E. Barnard, F.R.S., who made her own research possible by his invaluable assistance.

2. Sir James Purves-Stewart has stated quite openly that Miss Chevassut is the only person who is thoroughly conversant with the technique, which is highly complicated, and that she is the only one who is competent to make the vaccine satisfactorily. He stated in the *Lancet*[1] that as the result of it we are now enabled to *diagnose* disseminated sclerosis at an earlier stage than was formerly possible.

3. It is true that Miss Chevassut could not accept the invitation of the Medical Research Council to work at the National Hospital, or the request of Dr. Carmichael to demonstrate positive cultures there. The matter between Dr. Carmichael and Miss Chevassut she regarded as entirely a private concern, and on February 7th she agreed to co-operate with Dr. Carmichael as regards the demonstration of cultures, etc., under new conditions. Furthermore, in her original publication, in March, 1930, on the etiology of disseminated sclerosis, Miss Chevassut states that " transference of material either before culturing or before microscopical examination of the cultures is very undesirable ; such a procedure leads to unreliable and inconstant results." Having regard to this statement it is obvious that the " negative findings " were due to non-fulfilment of this primary condition laid down by her for the obtaining of positive cultures. Without exception, all the fluids received in the test series referred to were negative, in spite of an erroneous statement to the contrary. Miss Chevassut has on many occasions demonstrated to medical men of this country, and of foreign countries, the appearance she believes to be characteristic of cultures made from cerebro-spinal fluid in cases of disseminated sclerosis.

4. In his letter dated January 21st, 1931, to the chairman of the Halley Stewart Trust, Sir James Purves-Stewart writes in glowing terms of Miss Chevassut's work. The Trust refused an application for a grant of £20,000 to establish a separate unit for Westminster Hospital, where Miss Chevassut could carry on her work in neurological research. But the Trust is now establishing an independent institute at Hampstead, equipped with every modern appliance, in order to place her services at the command of the entire profession without favour to any individual or hospital. Consequently, when Sir James Purves-Stewart wrote to her demanding her presence at the laboratory to discuss the results of her " obstinate refusal " to obey his wishes regarding the National Hospital, she declined to comply with his demand, and wrote, finally dissociating herself from him. All the technical staff who worked with Miss Chevassut in the Westminster Hospital Neurological Research Laboratory are now working under the auspices of the Halley Stewart Trust in the new research institute.—I am, etc.,

B. HALLEY STEWART, M.D., B.Ch.,
Trustee, Halley Stewart Trust.

Totteridge, March 9th.

EPSOM COLLEGE

SIR,—The issue of a voting postcard, together with a very strongly worded recommendation, on the question of the abolition of voting for foundationers and pensioners at Epsom College raises, to my mind, another most important matter. Would it not prove a very beneficial plan both for the charity and for the school if they were separated, except as regards the actual education of the foundationers?

Legislation would be necessary before the trust funds, etc., could be handed over, but that should present no difficulty if there were an agreed scheme. The school would then be administered by a body partly nominated by such bodies as the British Medical Association, the Royal Colleges, and the Universities, and partly co-opted. The charity would be administered by (I would suggest) the Royal Medical Benevolent Fund. This society would be represented on the school governing body and would

[1] *Lancet*, March 15th, 1930, p. 564.

pay full fees for the foundationers. To my mind the advantages of this arrangement would be:

1. Economy—one London office instead of two.
2. One appeal to the medical profession instead of two.
3. No possibility of legal trouble as to which body is meant in a will—such trouble has occurred in the past.
4. The idea that all boys at Epsom receive charitable help would fade.
5. Investigation of the needs of pensioners, etc., would be carried out by one body instead of two.
6. The education of needy boys too young for Epsom could be arranged. The recent raising of the minimum age for foundationers emphasizes the desirability of this.

Probably other readers have some views on this subject. If so, it would be interesting to hear them.—I am, etc.,

Brentwood, Feb. 28th. H. G. L. HAYNES.

MARY SCHARLIEB MEMORIAL

SIR,—The memorial to Dame Mary Scharlieb, D.B.E., Litt.D., M.D., M.S., is to take the form of a ward in the new gynaecological and obstetrical unit of the Royal Free Hospital, which will bear her name and be for ever associated with the work in which she was the great and beneficent pioneer.

Mary Scharlieb was a student of the London School of Medicine for Women and the Royal Free Hospital from 1879 to 1882. She was appointed gynaecologist to the hospital, and was the first woman to be elected to the honorary visiting staff of this or any other general hospital in the kingdom. She filled the post with great distinction from 1902 to 1908. She was lecturer in midwifery from 1887 to 1913, and president of the school from 1918 to 1930. A year before her death on November 21st, 1930, it was decided that her name should be attached to the new unit, and the "Mary Scharlieb Ward" will fittingly connect her own work for women with the hope and healing to be brought to future generations of patients. We ask that those who appreciate the work which Mary Scharlieb did for humanity, and in particular for motherhood, will help to build this ward.

Subscriptions, including gifts from her family, who earnestly desire the success of this memorial, already amount to £620, and further donations should be sent to the Lady Sybil Smith, honorary treasurer of the Appeal Fund, 8, Hunter Street, Brunswick Square, W.C.1.—We are, etc.,

GERTRUDE KINNELL
Chairman

London, March 5th.

MEDICAL RECIPROCITY WITH FRANCE

SIR,—The only definite objection which has been raised by your correspondents to applying for medical reciprocity with France is that it would not be successful. That is surely not for us to determine. At present we are not receiving fair treatment, and the French Foreign Office, now directed by so sympathetic a head as M. Aristide Briand, would recognize that at once. At first the French medical faculty might raise objections, but if the application be limited to a small maximum number—say, to 50 or 100, which would meet the case—the objections would probably not be pressed, especially if it be made clear that climatic and thermal stations would profit, as heretofore, by the presence of one or more British medical men, who attract visitors, and so help the stations.

It seems monstrous that British medical men should be allowed to practise in Italy and excluded from France, especially when such easy terms are allowed to a Frenchman who desires a British qualification. Possible openings for British medical men abroad ought not to be thrown away by us on the lazy plea that it is no use trying to secure them. The Colleges, or the British Medical Association, would, I believe, secure a favourable hearing.—I am, etc.,

Menton, March 7th. D. W. SAMWAYS.

Obituary

DOUGLAS DREW, M.D., F.R.C.S.

Consulting Surgeon, Queen's Hospital for Children

Douglas Drew, whose death occurred at Cooden on February 25th, after a long and trying illness, was born in London in June, 1867, and received his early education at Amersham Hall, Reading, whence he matriculated at London University, and joined University College as a medical student. All his early professional studies were conducted at that institution, and there his bias towards surgery was encouraged and early determined by the award of the Atkinson Morley scholarship in surgery, and shortly afterwards by his appointment as surgical registrar and assistant demonstrator of anatomy at the hospital. He obtained the F.R.C.S.Eng. in 1892, and the M.D.Lond. in the same year. The first post outside the hospital to which he was appointed was resident medical officer at the Infirmary, Stoke-on-Trent, but at the conclusion of his term of office in this capacity he returned to London, and acted as private assistant to Sir Victor Horsley. In 1899 he was appointed assistant surgeon to the North-Eastern Hospital for Children, as it was then called, though subsequently renamed the Queen's Hospital for Children. Shortly after this he was appointed surgeon to the Hospital for Women, Soho. With both of these institutions he was connected at the time of his death, in the position of consulting surgeon.

Drew's surgical career in London was interrupted by the events of the South African war, which called for the volunteer services of experienced surgeons. He was offered, and accepted, the post of surgeon to the Imperial Yeomanry Hospital at Pretoria, where he profited by a very extensive experience in operative surgery. There he collected material for a very valuable paper on "The extraction of a bullet from the motor region of the brain," which was published in the *British Medical Journal* in 1902. His contributions to surgical literature, though very much to the point, were not numerous. He always felt much more at home at the operating than at the writing table; in fact, he took very little trouble to disguise his contempt for those whose success mainly depended on the arts of publicity or advertisement, and he probably made more than one enemy by his outspoken expressions of disapproval of such methods. His best surgical successes were made in connexion with operations for malignant disease of the rectum, and he was one of the pioneer exponents of the method of radical excision of malignant disease of the breast by the simultaneous removal of the pectoral muscles and underlying tissues. In the days when excision of the hip was practised for tuberculous disease, he carried out this procedure in a large number of cases at the Queen's Hospital for Children, and acquired a great reputation for his skill and technique in this difficult operation. He also obtained many successes in the removal of haemorrhoids by a special method of his own designing. In 1919, when the London County Council was making arrangements with the voluntary

hospitals for the treatment of school children, he did good service to the cause of child welfare by insisting that the operation for the removal of tonsils and adenoids was not a trivial procedure to be lightly undertaken, but one that required as much care in the after-treatment as many a major operation.

Towards the end of 1914 his career as an active operating and hospital surgeon practically came to an end through a serious illness which necessitated several operations. Shortly afterwards, he retired from whole-time work in London and took up partial residence in Cooden near Bexhill, where, as far as the painful and severe nature of his infirmities allowed, he conducted a considerable consulting practice. During a prolonged and very painful illness he showed remarkable courage by undertaking large and important operations which caused great bodily distress and fatigue. He also carried out under the same difficult circumstances a considerable amount of war work at King George's War Hospital, as well as at the local war hospital at Cooden. Apart from his purely professional work, Douglas Drew did good service to his medical brethren in the capacity of vice-president of the Medical Defence Union (1904), and as an elected member of the council from 1922 until 1928, when he resigned owing to ill-health. He played a particularly active part in the defence of Dr. Mary Thorne in 1904, one of the many medical victims of judicial misunderstanding.

In social life Douglas Drew was a very popular man, and he had a very large circle of friends both in London and in Cooden. He was an esteemed member of both the Savile and Arts Clubs, where he spent a good deal of his time when in London after his semi-retirement to Cooden. He was a very successful gardener, a keen fisherman, and a good though somewhat temperamental golfer. On river or golf course his manual dexterity and neatness of fingers stood him in good stead. His natural impetuosity, which occasionally manifested itself in the serious affairs of life as well as during his lighter occupations, has been anonymously immortalized in one of Mr. A. C. M. Croome's best golfing stories (*Pall Mall Gazette*, June 3rd, 1906), which refers to an incident in which Douglas Drew was the unconscious hero. He was particularly happy and fortunate in his family life, and leaves behind him a devoted wife, one son, and one daughter.

STANLEY EDWARD DENYER, C.M.G., M.D., F.R.C.S., M.R.C.P.

Consulting Physician, Hull Royal Infirmary

By the death of Dr. Stanley E. Denyer the medical profession in Hull has lost a very distinguished member, at the age of 61. His medical degrees and diplomas showed much versatility, including as they did the M.D. and M.A. of Cambridge, the M.R.C.P.Lond. and F.R.C.S. Eng., and the D.P.H. of the English Conjoint Board. At Cambridge he was demonstrator and examiner in anatomy, and director of studies in natural sciences at Queen's College. At Guy's Hospital he was pathological assistant, and held the Gee Fellowship. In the South African war, serving in the R.A.M.C., he was awarded the C.M.G. and the South African medal with five clasps. In the great war he became medical inspector of the Humber garrison, and was later, at Alder Hey Hospital, on the staff of Sir Robert Jones, who spoke of him enthusiastically as "one of our great assets." He was twice mentioned in dispatches. In Liverpool University he was temporarily lecturer in anatomy.

For the last sixteen years Dr. Denyer had been in practice in Hull, including ten years as honorary physician to the Royal Infirmary. His keen interest in clinical medicine was shown by his industrious hospital work, by his regular participation in all clinical meetings, and by his articles in the medical journals. He felt strongly that the value of the scientific clinician—particularly in collating and focusing the many-sided evidence—was at present greatly underestimated. He served as librarian and as president of the Hull Medical Society, and as chairman of the East Yorks and North Lincolnshire Division of the British Medical Association. Up to the end he was one of the representatives of the Division at the Annual Meetings of the Association.

Perhaps the outstanding features of his personal character were enthusiasm and an industry unsparing of self. He was an excellent colleague, was beloved of his patients, and had a happy way with children. He was very fond of the country, and at any beauty spot within reach of Hull his large touring car might often be seen unloading his young family for a picnic. He leaves a widow, two sons, and three daughters, one recently married in South Africa.

Dr. RALPH SMITH MILLER, who died at Codford, Wilts, on February 16th, was born in January, 1861, the son of William Miller of Shotts, Lanarkshire. He studied medicine at Edinburgh University, where he graduated M.B., C.M. in 1883 and M.D. in 1889. He started practice at Tollerton, Easingwold, Yorkshire, where to this day he is remembered with gratitude by many of his old patients. Later, he was invited to undertake a locumtenency at Kiu-Kiang on the Yang-tse-Kiang for eighteen months, and on completion he joined, as a partner, Dr. T. C. Thornicraft at Kobe, Japan, where he remained for twenty-five years. He then specialized in the treatment of drug addicts, and eventually took up practice in London, until a breakdown in health compelled him to retire from active work six years ago. He is survived by one son and two daughters, his wife having predeceased him. Dr. Miller was a man of rare charm of manner and acute insight into human nature. His passing will be regretted by his many friends and patients.

Dr. JULIAN HORA died on February 25th, aged 60. He was the son of Mr. H. W. Hora, a deputy of the City of London and a member of the Common Council for Portsoken Ward. He was educated at Guy's Hospital Medical School, and graduated M.B., B.S.Lond. in 1895, in which year he also took the diplomas of the English Conjoint Board. He was formerly medical officer to King's Norton Union Workhouse and Infirmary, assistant house-surgeon to the Cardiff Infirmary, and assistant medical officer at the County Asylum, Prestwick. He had been in practice at Cambridge Road, E., for over twenty years. Dr. Hora, who was a freeman of the City of London, is survived by his wife and two daughters.

The death took place at St. Andrews, on February 26th, of Dr. DAVID LENNOX, who had been lecturer and reader in forensic medicine at University College, Dundee. Born in 1859, Dr. Lennox graduated M.B., C.M. at Edinburgh in 1880, proceeding to the degree of M.D. in 1884. For a time he was surgeon, R.N., and was for many years lieutenant-colonel in the R.A.M.C.(T.F.), being awarded the Territorial Decoration for length of service. He took much interest in anthropology and antiquarian questions, and was a Fellow of both the Royal Anthropological Institute of Great Britain and of the Society of Antiquaries of Scotland. He published a small work on the elements of physical education, and contributed an article on the evolution of race in Forfarshire to the *British Association Handbook*, 1912. The interment took place on March 2nd in the Western Cemetery, St. Andrews, after a service in the University Chapel, which was attended by a large number of representatives of the University teaching staff.

Dr. JAMES CAMERON died on January 11th at the Beverley Cottage Hospital from septicaemia following an accident on Christmas Day. He was the elder son of the late Dr. James Cameron, who practised at Braemar and afterwards at Batley Carr, Dewsbury. Receiving his early education at Batley Grammar School, he studied medicine at Edinburgh University and the London Hospital. He graduated M.B., C.M.Ed. with honours in 1887, and proceeded to the M.D. in 1894. He also took the M.B. degree of London University in 1900 and the M.D. in 1910. After holding several appointments in Scotland he became a ship surgeon, in which capacity he made many voyages to India, China, and other parts of the world. He was an accomplished Gaelic scholar and was proficient in eight languages—including Hindustani and Chinese. In 1914 he received a temporary commission in the R.A.M.C., retiring at the close of the war with the rank of captain. He succeeded to the practice of the late Dr. Watson of Beverley about five years ago, and soon became popular in the district. He was medical officer to the Beverley Cottage Hospital, and a member of the East Yorkshire Division of the British Medical Association.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The House of Commons discussed this week the Estimates for the Army and Navy; discussion on those for the Air Force was postponed. A motion was carried approving the adherence of the United Kingdom to the Act for the Pacific Settlement of International Disputes, and a debate was arranged on India.

In the House of Lords the second reading of the Pharmacy and Poisons Bill was set down. Lord Ponsonby has taken charge of this measure in succession to the late Earl Russell, and Lord Dawson of Penn proposed to speak on it.

Next week the Parliamentary Medical Committee will meet to discuss a Bill for the regulation of proprietary medicines.

In the House of Lords, on March 10th, the Yarmouth Naval Hospital Bill passed through committee.

The Protection of Dogs Bill, the Nursing Profession (Wages and Hours) Bill, and the Hospitals (Relief from Rating) Bill were down for second reading on March 6th, but were not reached. This was the last day available for second readings of private Bills.

Small-pox and Vaccination

In reply to Mr. Freeman on March 5th, Mr. GREENWOOD stated that the total numbers of deaths of children under 2 years of age in England and Wales which were registered in the years 1911-30 and classified to vaccinia and small-pox respectively were 37 and 64. In addition, there were 99 deaths in regard to which reference was made to vaccination either on the medical certificate or in reply to inquiry from the Registrar-General.

Mr. GREENWOOD told Dr. Fremantle, on March 5th, that local authorities were charged at the rate of 6d. a tube for lymph for use in their institutions. No charge was made to public vaccinators or medical officers of health. The gross and net costs of the Government lymph establishment for the year 1929-30 were approximately £15,000 and £13,000 respectively. Asked if there was any reason why public authorities who used this lymph should not be charged, and that charge set against the cost of the establishment, Mr. Greenwood said it was the common practice for public vaccinators to make no charge, and public institutions charged only a low fee.

Immunization of Cattle against Tuberculosis

Answering Sir A. Sinclair on March 5th, Dr. ADDISON said his attention had been drawn to experiments carried out by M. Spahlinger on a farm in Norfolk by Captain Richard Buxton, who had presented him with a summary of the report on experiments. He had suggested to him that in the interest of all concerned there should be a complete test by and under the independent control of recognized authorities who are experienced in research in tuberculosis. Research work was being actively carried on at the Research Institute of Animal Pathology, Cambridge, and at the Ministry's Veterinary Laboratory, Weybridge, with a view to devising an effective and cheap method of immunizing cattle against tuberculosis. The Calmette and other methods were being studied. Future plans depended to a large extent on the result of research work now in progress.

Dr. ADDISON told Mr. Hurd, on March 9th, that he was informed that the Minister of Agriculture for Northern Ireland had not yet issued a report on the progress of the tests of the efficacy of serum treatment for bovine tuberculosis which were being carried out by the Government of Northern Ireland.

Paratyphoid in Essex

In reply to a question put by Mr. Groves on March 4th concerning the outbreak of paratyphoid fever at Epping, Mr. GREENWOOD said that a medical officer of his Department visited the district on February 10th and made a brief report on that day. The farm hand who was suspected of being a carrier ceased handling the milk on January 24th and was removed to hospital on February 11th; 223 cases of paratyphoid were notified in the Epping urban district and neighbouring districts between February 10th and 28th, some of these being cases of delayed notification. A few further cases were notified as late as March 2nd.

National Insurance Funds.—Mr. GREENWOOD told Major Beaumont Thomas on March 5th that the total amount of accumulated funds in hand in Great Britain under the National Health Insurance Acts at December 31st, 1929, was £126,000,000 approximately. The interest accrued during the year ended December 31st, 1929, was £5,600,000, and the cost of administration—including central administration—for the year was £5,400,000.

River Pollution.—Replying to Mr. Ramsbotham on March 5th, Mr. GREENWOOD said he had received two applications from county councils, under Section 14 of the Local Government Act, 1888, for setting up joint committees to enforce the provisions of the Rivers Pollution Prevention Acts. When the catchment boards appointed under the Land Drainage Act, 1930, had had a reasonable time to function, he proposed to review the position in the light of the power conferred on him by that Act of taking the initiative in securing establishment of joint committees for preventing pollution.

Rate-aided Mental Patients.—In reply to Mr. Sorensen on March 5th, Mr. GREENWOOD stated that local authorities were entitled under the statute to recover expenses of maintenance against the property of rate-aided mental patients. He was not empowered to prevent such action. He would make inquiries into any specific case of hardship.

Medical Officers on the Gold Coast.—Dr. SHIELS told Mr. Rennie Smith on March 4th that there were twelve women medical officers in the service of the Gold Coast Government, of whom one was an African. There were also a few European women doctors working with missionary societies in the Colony. There were no facilities in the Gold Coast for students of either sex to undergo locally the training necessary to qualify as medical practitioners. In the case of Government medical officers, the same facilities for post-graduate training were provided for both men and women doctors. There was no difficulty in meeting the demand for women medical officers for Government service.

Experiments on Dogs.—Mr. CLYNES told Mr. Freeman on March 5th that there was no record of the number of dogs used for the purpose of vivisection, but no dogs were used for this purpose at the Royal Veterinary College in 1930.

Housing.—Replying to Mr. Somerville Hastings on March 5th, Mr. GREENWOOD said that 117 areas in England and Wales, occupied by 24,237 persons, had been declared to be clearance areas under the Housing Act, 1930. These declarations did not require his sanction. Mr. Greenwood said he

was not satisfied with the progress made, and would not be for a long time, but pressure was being exercised on those local authorities whose programmes did not appear to be commensurate with their needs.

Foot-and-Mouth Disease.—Dr. ADDISON, on March 2nd, said that ten cases of foot-and-mouth disease, distributed between six separate centres, had been confirmed by the Ministry of Agriculture during the six months ended February 26th last. In none of the initial cases was it possible definitely to identify the origin of infection.

Notes in Brief

India's opium exports in 1927 were 1,120,900 lb.; in 1928, 1,008,635 lb.; and in 1929, 888,801 lb.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

At a congregation held on March 7th the following medical degrees were conferred:

M.B., B.CHIR.—T. I. Evans.
M.B.—C. J. Grosch.

UNIVERSITY OF LONDON

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

The following passed the examination at the eighty-ninth term (October, 1930, to February, 1931):

*T. T. Mackie (Duncan Medal), *N. J. Abbensetts, *J. Cairns, *S. Dakshinamurty, *W. P. Jones, *R. M. Kasliwal, *E. W. Martindell, *M. Noronha, *R. B. Wallace, *J. Welch, A. J. Abeyesundere, E. R. Abeyesundere, F. V. Adams, A. S. Agbaje, M. Akram, C. D. Amarasinha, J. Barclay, L. Brown, H. G. Calwell, O. P. Campion, M. M. U. D. Chughtai, G. J. Clarke, A. E. Connan, T. F. Crabbe, T. H. Dalrymple, W. C. E. Diamond, R. F. G. Dickson, M Edwards, D. Ellis, H. G. Floyd, A. J. Garde, J. R. Jensen, R. A. B. Leakey, Ah Ma, P. B. P. Mellows, W. E. S. Merrett, B. A. Moss, S. Noronha, L. D. Pringle, J. A. S. de Sampayo, M. Sangarapillai, C. F. W. de Saram, D. W. Semmens, J. M. Shapiro, S. Thambiah, D. P. Turner, E. M. Weir, G. F. West, R. N. Wilcox, W. A. Wilson, W. E. S. Winn.

* With distinction.

UNIVERSITY OF BIRMINGHAM

Miss K. M. Maclaren, M.R.C.S., L.R.C.P., has been appointed as researcher in tissue culture, and Mr. C. J. Bond, F.R.C.S., as William Withering lecturer for 1932.

UNIVERSITY OF LIVERPOOL

The title of Professor Emeritus has been conferred upon Dr. Walter Ramsden, who recently resigned the Johnstone chair of biochemistry.

NATIONAL UNIVERSITY OF IRELAND

The degree of M.D. has been granted to Joseph A. O'Flynn, M.B., B.Ch., B.A.O.

Dr. Theobald W. T. Dillon has been appointed professor of medicine at University College, Dublin, and Dr. Charles C. O'Malley professor of ophthalmology and otology at University College, Galway.

Dr. Denis J. Coffey has been appointed to represent the University at the celebrations of the fourth centenary of the Collège de France, to be held in Paris in June, and Professor William D. O'Kelly will be the representative at the Conference of the National Association for the Prevention of Tuberculosis at Margate in June.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Macloghlin Scholarships

Mrs. Eliza Macloghlin, who died in May, 1928, left by her will to the Royal College of Surgeons a sum of money for the purpose of founding and endowing scholarships for medical students, in memory of her husband, the late Mr. E. P. P. Macloghlin, M.R.C.S., formerly in practice at Wigan. One scholarship, tenable for five years, of an approximate value of £100 per annum, is awarded annually in July. The scholarships are given to candidates, between the ages of 16 and 22, whose means would otherwise be insufficient to cover the cost of medical education. In 1930, at the first competition, there were five candidates.

Forms of petition, completed by intending candidates, must reach the secretary of the College not later than June 1st. They must be accompanied by: (1) a duly certified copy of the register of birth of the petitioner; (2) a testimonial of character and conduct from the head master of his school; (3) a certificate of having passed a preliminary examination in general education recognized by the Conjoint Examining Board for admission to its pre-medical examination. The pre-medical examination for which candidates will be required to sit will be held on June 30th and following days. Copies of the regulations relating to the award of the scholarships and forms of petition may be obtained from the secretary, Royal College of Surgeons, Lincoln's Inn Fields, W.C.2. Copies of the regulations of the Conjoint Examining Board in England relating to the pre-medical examination, with synopses indicating the range of the examination in chemistry and physics, may be obtained from the secretary, Examination Hall, Queen Square, W.C.1.

Medico-Legal

EXTREME DEAFNESS A DISABILITY FOR MOTOR DRIVERS

Tests for hearing were not much considered during the discussions which took place last year on the physical fitness of motor drivers, but a case which came before the Lord Mayor of London (Sir W. Phené Neal) at the Mansion House police court on March 5th raised the question in an acute form, and it was decided by his lordship that extreme deafness was a "physical disability" within the meaning of the Road Traffic Act, 1930, such as rendered the driver of the motor vehicle a source of danger to the public.

According to the police, the defendant was driving dangerously in Ludgate Circus, and on being stopped it was discovered that he was so deaf that only his wife could make him understand. He was a foreigner who had been living in the Canary Islands for some years, and did not know the London traffic regulations. The summons was dismissed on payment of costs.

Section 5 of the Road Traffic Act requires an applicant for a licence to make a declaration in the prescribed form as to whether or not he is suffering, not only from any disease or physical disability specified in the form, but from any other disease or physical disability likely to cause the driving of a motor vehicle by him to be a source of danger to the public.

Medical News

The St. Patrick's Day dinner of the Irish Medical Schools' and Graduates' Association will be held this year at the Piccadilly Hotel, on March 17th, at 7.30 for 7.45 p.m. The guest of honour will be Lord Russell of Killowen.

Sir Percy Sargent will deliver the Harveian Lecture on "The romance of the pituitary gland," before the Harveian Society of London, on Thursday, March 19th, at 8.30 p.m., at 11, Chandos Street, W.1. The lecture will be illustrated by lantern slides. The society extends a cordial invitation to all practitioners to attend.

The Tuberculosis Association will hold a provincial meeting at Oxford on March 26th, 27th, and 28th. On the first day there will be a discussion on stereoscopic and postural radiography of the chest. On March 27th, at 10 a.m., Dr. Jacquerod will read a paper on the natural processes of healing in pulmonary tuberculosis, and at 5 p.m. Drs. L. S. T. Burrell and N. Tattersall will open a discussion on the future of artificial pneumothorax treatment. On the last day of the meeting, Mr. H. Morriston Davies will show a cinematograph film of thoracoplasty, and Dr. J. Crockett will discuss gelatino-thorax; there will also be an exhibition of *x*-ray films. The meetings will be held in the Dunn Laboratory, South Parks Road. Further information may be obtained from the honorary secretary, Dr. G. T. Hebert, Tuberculosis Department, St. Thomas's Hospital, S.E.1.

At the meeting of the Child Study Association to be held at 90, Buckingham Palace Road, S.W., on April 16th, at 6 p.m., Dr. J. Norman Glaister will read a paper entitled "Does the developing mind recapitulate ancestral history?" On May 7th a discussion on "The nursery school" will be opened by Miss E. Stevenson.

The London Clinical Society will hold a clinical evening, at the London Temperance Hospital, on Tuesday, March 17th, at 8.45 p.m.

Particulars of the lectures and demonstrations arranged for next week by the Fellowship of Medicine will be found in our Diary of Post-Graduate Courses, published in the *Supplement* at page 84. Copies of syllabuses and tickets of admission can be obtained from the Fellowship, 1, Wimpole Street, W.1.

A three months' course of lectures and demonstrations on clinical practice and in hospital administration for the diploma in public health will be given at the North-Eastern Hospital, St. Ann's Road, Tottenham, N.15, by the medical superintendent, Dr. F. H. Thomson, on Mondays and Wednesdays at 4.15 p.m., and alternate Saturdays at 11 a.m., beginning on Wednesday, April 8th. The fee for the course, which complies with the revised regulations of the General Medical Council, is £4 4s. A course under the old regulations may be taken for £3 3s.

At a meeting of the British Institute of Philosophical Studies to be held at the Royal Society of Arts, 18, John Street, Adelphi, W.C., on Tuesday, March 17th, at 8.15 p.m., Mr. R. G. Collingwood will give a lecture entitled "The purpose of aesthetics." Cards of admission may be obtained from the Director of Studies, University Hall, 14, Gordon Square, W.C.1.

The following members of the medical profession were among those elected Fellows of the Royal Society of Edinburgh on March 2nd: Dr. W. R. D. Fairbairn, lecturer in psychology, University of Edinburgh; Dr. J. du P. Langrishe, lecturer in public health, University of Edinburgh; Dr. J. B. McDougall, medical director, British Legion Village, Preston Hall, Kent; and Mr. J. J. McIntosh Shaw, lecturer in clinical surgery, University of Edinburgh.

We are asked to state that hospitals situated within eleven miles of St. Paul's desiring to participate in the grants made by King Edward's Hospital Fund for London for the year 1931 must make application before March 31st to the honorary secretaries of the Fund at 7, Walbrook, E.C.4 (G.P.O. Box 465A). Applications will also be considered from convalescent homes which are situated within the above area or which, being situated outside, take a large proportion of patients from London.

The next congress of the Jugoslavian Dermatological Society will be held at Belgrade in May next, under the presidency of Professor Gjorgjevic.

In connexion with the sixth International Congress of Thalassotherapy, which will be held at Berck-sur-Mer from May 25th to 30th, visits will be arranged to the Artois battlefields, the northern weaving manufactures at Tourcoing and Roubaix, and to other centres of interest. Communications are invited from British practitioners on the treatment of coxalgia and its complications by climatic and hydrotherapeutic measures. The congress fee for non-members of the Association of Thalassotherapy is 60 francs. Further information may be obtained from the secretary, Dr. Mozer, Hôpital Maritime de Berck-Plage, Pas-de-Calais, France.

The annual congress known as the Journées Médicales de Lille will be held at Lille on May 2nd and 3rd.

The second International Congress of Sanitary Technique and Urban Hygiene will be held at Milan from April 20th to 25th, and will consist of six sections, devoted respectively to general questions of public and private hygiene, urban sanitary technique, sanitary technique of houses and public buildings, rural and colonial sanitary technique, sanitary technique of shops and laboratories, and urban, industrial, and rural sanitary technique. Further information can be obtained from the general secretary, Piazza del Duomo 17, Milan.

Dr. Wu Lien Teh has given 20,000 taels (£3,000 sterling) to the Royal-Asiatic Society, China, towards the rebuilding of the Institute in Shanghai which maintains libraries and facilities for the encouragement of co-operation between Chinese and Western thought. This gift is an expression of gratitude for the help that Dr. Wu Lien Teh (then G. L. Tuck) received when, in 1896, he was awarded a Queen's Scholarship of £200 a year from the Straits Settlements, and was thus enabled to secure his education in English medicine at Emmanuel College, Cambridge, and subsequently at St. Mary's Hospital, London. Dr. Wu Lien Teh now holds positions of high responsibility under the National Government in China, having been appointed in 1930 as chief technical expert of the Ministry of Health, and director-general of the National Quarantine Service based at Shanghai, while he still retains charge of the North Manchurian Plague Prevention Service, for which he was chosen in 1912.

The Fight Against Disease is published quarterly by the Research Defence Society, and placed on sale by Macmillan and Co., Ltd., price 6d. The last issue (Winter, 1930–31) includes a note on the use of animals for the standardization of remedies, by Dr. J. H. Burn, and an appreciation, by Professor Winifred Cullis, of the late Dame Mary Scharlieb, who up to the time of her death was keenly interested in the work of the society, and remained a member of its general committee.

Dr. Rouvière, professor of anatomy in the Paris faculty of medicine, has been elected a member of the Académie de Médecine.

The fourth centenary of the Collège de France will be celebrated from June 18th to 20th inclusive.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Miscarriage of One Twin

Dr. A. Boyd Roberts (London, W.9) writes: About a year ago I was called to treat Mrs. C. for a miscarriage, and found that a foetus and placenta had been expelled. It was apparently a four weeks' pregnancy. The mother, who already had one child, six years old, was quite conscious that she was still pregnant following the miscarriage. Two months later I was called again, and diagnosed a three months' pregnancy. On November 13th I delivered the patient of a fully matured female child. I take it that there were two separate placentas and that the expulsion of the first did not destroy the second. Is not this miscarriage of one of a twin pregnancy very uncommon? It would be interesting to know the experience of other practitioners in such cases.

Income Tax

Colonial Appointment—Remittances

"C. C." is employed in West Africa, and usually visits the United Kingdom, where he maintains a home, every twelve months. He pays British income tax on that portion of his earnings which he sends or brings to this country. He will not, however, be in the United Kingdom between March 25th, 1930, and April 25th, 1931. Will he be liable to income tax here in respect of the financial year ending April 5th, 1931?

*** No. During a year in which "C. C." does not return to the United Kingdom his wife is liable to taxation as a feme-sole, but only in respect of remittances made to her out of "property"; remittances made out of the husband's earnings do not fall within that category, and in such circumstances are not liable to British income tax.

Replacement of Car

"C. H. C." bought a car in 1920 for £550, and in January, 1931, sold it for £20, and bought a new car for £237 10s. Depreciation has not been claimed for income tax purposes. The car is used only partly for professional visits, and only one-half of the running cost has been debited to professional earnings. What can he claim?

*** He can claim as a professional expense a reasonable proportion (apparently one-half) of the out-of-pocket cost of replacement—that is, one-half of £217 10s. = £108 15s. That amount will have to be regarded as expended in January, 1931; consequently, if he makes his statement of accounts out to December 31st the deduction will affect his profits for the year 1931 and his income tax liability for the year 1932–33, but if his annual accounts are made out to, say, March 31st, then it will operate to reduce his liability for 1931–32.

First Year of Partnership

"C. D." became a partner in a firm as from April 1st, 1930; prior to that date he had been acting as a locumtenent. How should his liability for 1930–31 be calculated?

*** He will be liable to account for tax on his share (less his personal allowances, etc.) of the firm's gross assessment for 1930–31, and that assessment will presumably be calculated in the usual way on the amount of the profits earned in 1929–30 by the then existing firm. His liability to assessment as a locumtenent does not extend to periods subsequent to April 1st, 1930.

LETTERS, NOTES, ETC.

Mammary Abscess

"SUBURBAN G.P." writes: Within the past few weeks I have had three cases of mammary abscess occurring in primiparae three to five weeks after confinement. All the patients had been confined at a maternity home under excellent conditions, and were discharged after a normal fourteen days' puerperium. Breast abscess results in a good deal of distress, physical and domestic, while the life of the young infant can be seriously jeopardized; it may be a question of months before the mother completely recovers. In searching for a possible causation I feel strongly that the application of hardening agents—for example, spirit—to the nipple ante-natally may constitute a weak link in the chain of ante-natal "do's" and "don'ts." Curiously enough, the left breast was involved in each case. I do not offer any explanation, but I should be glad to know the opinions of some of your more experienced readers.

Graves's Disease: Intercurrent Pyrexia

Dr. J. G. BENNETT (Hyde, Cheshire) writes: Of late we have had quite a number of demonstrations illustrating the effect of one disease upon another, often with a markedly beneficial result. Of such a type is the benign alteration which ensues when suitable cases of general paralysis of the insane are inoculated with the virus of malaria. I have a case which illustrates a similar phenomenon, but here the primary disease is exophthalmic goitre. The patient is a cotton cloth tester, and he is a typical sufferer from moderate Graves's disease, having all the cardinal signs of the complaint, including a constantly rapid pulse, usually 110 to 120 per minute. There is also extrasystole. As a rule he can do his work well, and for his age (62) he does not suffer great handicap. Whenever he gets an influenzal cold, with its subsequent deflorescent perspiration, the latter heralds a wonderful slowing and regularity of his pulse. For weeks after such an attack his heart beats regularly and slowly, he feels in splendid condition, and can work much better and with less fatigue than before the attack. This beneficial result has occurred on four or five occasions since I first treated him ten years ago, and the connexion between the two diseases is, to my mind, undoubted. Whether the antibodies brought into being by his influenza have neutralized toxin due to the exophthalmic goitre, or whether the influenza has reduced secretion at its source in the thyroid gland, I do not know, nor can I say whether treatment on these lines in every case of Graves's disease would be a specific, but the phenomenon appears to me to be well worth further investigation in the laboratory.

A Twin Monster

DR. M. Y. LUM (Kuala Lumpur) reports the birth, on September 19th, 1930, in the Chinese Maternity Hospital, Kuala Lumpur, of a double monster. The first head delivered was followed by the corresponding arms. Then the breech had to be extracted manually. The breech of the second child was delivered next, followed by the head. Dr. Lum adds: There was only one placenta, and one cord, which was attached to the lower surface of the band connecting the twins; the connecting band measured 10 inches in circumference. The twins were healthy, and weighed 8½ lb. together. There was a distinct systolic murmur in the smaller child. Both children had to be fed independently. The parents, poor vegetable gardeners, sold the twins to a friend, who put them up for exhibition on the tenth day. In consequence, apparently, of continuous exposure and bad artificial feeding, the twins contracted diarrhoea and fever on the eighteenth day, and died on the twenty-first day after birth. The smaller one died first, followed three hours later by the larger one. At the post-mortem examination all the organs were found separate, with the exception of the livers, which were so closely joined together that there was only a faint line of demarcation. There were two gall-bladders. The foramen ovale was patent in the smaller child. The photograph reproduced was taken on the fourth day after birth; the smaller child is on the right.

Pronunciation of Laboratory

"M.A., M.B." writes: The B.B.C. has adopted the very ugly pronunciation of laboratory thus, labōratory. All the eminent scientists at the studio talks have adhered to the old form labŏrătŏry, including Lord Moynihan and Sir William Bragg. It would be ugly were we to say elabōrate, and equally ugly is the pronunciation of rātions as rătions, as the B.B.C. studio has pronounced it.

Treatment of Addison's Disease

Several cases of Addison's disease have been treated in this country with extract of suprarenal cortex prepared according to the process of Swingle and Pfiffner (*Science*, March 21st, 1930). Messrs. Allen and Hanburys inform us that they have a limited supply of this extract, particulars of which can be given on application.

Corrigendum

The Librarian of the Liverpool Medical Institution writes: The paper read at this institution entitled "Cardiac output and oxygen utilization in heart disease" was the joint work of Drs. I. Harris and I. J. Lipkin. Owing to an oversight Dr. Lipkin's name was omitted in the account of the meeting sent for publication and appearing in the *British Medical Journal* of February 28th.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 50, 51, 52, 53, 54, 55, 58, and 59 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 56 and 57.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 83.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

239 Respiratory Disorders and Dental Infection

Discussing the part played by diseased teeth in the causation of various respiratory disorders, W. LINTZ (*Med. Journ. and Record*, January 21st, 1931, p. 62) records a series of 100 patients, and concludes that focal dental infections give rise to respiratory affections through the circulation, and not as the result of aspiration. Bacterial sensitization and autogenous immunization are, moreover, important factors in respiratory allergic conditions. Without radiological examination it is impossible to be certain that dental disease is not present. In the author's series the average loss of teeth for pleurisy was 37.5 per cent., for bronchial asthma 37 per cent., for tuberculosis 25 per cent., and for bronchitis 15.75 per cent., the normal figure for the general population. In the case of asthma, Lintz found that the best results were obtained only after the eradication of all focal infection and the immunization of the patient with an autogenous vaccine prepared from the saliva or the pus from decayed teeth sockets. He adds that the same holds good in hay fever. Immunization before dental extraction averts the occurrence of aggravated symptoms.

240 Uraemia without Kidney Disease

P. MEYER (*Klin. Woch.*, January 24th, 1931, p. 155) refers to several recorded cases in which prolonged vomiting led to uraemic symptoms, sometimes with convulsions. Diagnosis is rendered difficult by the presence of a high non-protein nitrogen and uric acid content of the blood, and in some cases also by the presence of albuminuria or anuria. At the necropsy no significant changes are found in the kidney. Meyer records two cases in detail; in one the vomiting was due to malignant pyloric stenosis, and in the other to the occurrence of a "vicious circle" after gastro-enterostomy. The second patient recovered rapidly on insulin and carbohydrates, and the blood non-protein nitrogen fell from 163 to 31 mg. per 100 c.cm. in five days. The author discusses the possible parts played by acidosis, chloride loss, dehydration, and starvation in the causation of the syndrome. The high non-protein nitrogen may, he thinks, be an attempt at compensation for the loss of other crystalloids (especially sodium chloride), or may represent breakdown of proteins owing to starvation. Anuria due to dehydration will increase the blood nitrogen still further. The occurrence of albuminuria is possibly due to a change in the constitution of the blood proteins.

241 Localization of Myocardial Infarction by the Electrocardiogram

T. PADILLA and P. COSSIO (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, January 16th, 1931, p. 54) refer to earlier investigations in which the electrocardiographic modifications characteristic of myocardial infarction have been established. The usual changes are an early alteration in the ST or RT segment, and, later, deformity or inversion of the T-wave. From a study of 35 patients, of whom 25 were observed and examined by the electrocardiograph at the onset of the illness, the authors describe the features representing apical infarctions and those corresponding to necrosis at the base of the ventricles. In the former group there is an initial convexity of the RT segment upward in Lead I and downward in Lead III, leading later to inversion of the T-wave in Lead I. In basal infarctions the initial deviation of the RT segment is downward in Lead I and upward in Lead III; consequently, in the later stages an inversion of the T-wave in Lead III develops. Occasionally it is found that the electrocardiographic changes indicate myocardial infarction while suggesting no definite apical or basal localization. In such patients certain other electrical anomalies not in themselves characteristic of infarction may give some information as to the site of necrosis. These are extrasystoles, defects in conduction of the bundle of His or of its branches, and auricular fibrillation. The various grades and varieties of heart-block are of most value in localization, and the authors describe a case in which complete heart-block associated with a basal type of ST deviation pointed to thrombosis in the right coronary artery, leading to infarction in the upper part of the posterior wall of the left ventricle and the septum. Auricular fibrillation has also been observed in association with curves pointing to basal necrosis, but this arrhythmia and that due to extrasystoles are of doubtful value in localization.

242 Incidence of Diphtheria

BÜRGERS (*Deut. med. Woch.*, January 2nd, 1931, p. 6) cites statistics to show that diphtheria has presented an increased incidence and severity in recent years throughout Europe. It is noteworthy that the last peak of epidemic diphtheria in Germany was during the years 1849–80, and in America in 1860–81; subsequently the curve fell, reaching its lowest level in 1923. Although diphtheria is known to have been very prevalent in the 16th and 17th centuries, too little is established about the behaviour of this infection to justify precluding a fresh rise during the next thirty years of the present century. Bürgers thinks it best in any case to contemplate the possibility of such an occurrence, and to institute prophylactic methods accordingly, especially in the form of active immunization by inunction. He adds that the fact that the increased incidence of diphtheria during the war was strictly circumscribed and only of transient duration, while the latest outbreak has involved almost every district in Prussia and considerable parts of Europe, should at least awaken apprehension.

Surgery

243 Surgical Treatment of Goitre

J. L. DE COURCY (*Amer. Journ. Surg.*, December, 1930, p. 482) discusses the surgical aspects of goitre, including pre-operative and post-operative care, the anaesthesia of choice, and the results of thyroidectomy in a large number of cases. Lugol's solution, in 10-minim doses, was given three times a day for the first ten days, and continued up to the time of operation and throughout the post-operative reaction, after which 10 minims were given daily for eight weeks. This procedure has been found of great benefit, the surgical mortality being reduced to 1 per cent. and the pre-operative mortality to 0.2 per cent.; it controls the symptoms, lowers the metabolic rate, and renders the thyroid gland oedematous, thus putting the secreting cells out of action and preventing the absorption of toxic substances. The most satisfactory form of anaesthesia in goitre operations was found to be nitrous oxide and oxygen. Treatment of toxic goitre must be by thyroidectomy; in mild cases a one-stage bilateral partial lobectomy may be performed, the wound being closed without drainage, but for very large hyperplastic thyroids a two-stage operation is desirable. If thyrotoxicosis is to be relieved completely, not less than four-fifths of the glandular substance must be removed, and in all cases extreme gentleness is required in handling the gland. In a series of 388 operations, 92 per cent. of which were for cases of toxic goitre, there was only one death. It has been found that thyroidectomy was of value in cases of mental disturbance associated with goitre, and of fourteen patients so treated, twelve have made complete mental recoveries; in thirteen of these patients there was a hyperplastic goitre. Mental improvement was gradual during a period of several months.

244 Treatment of Urethral Stricture

In tight strictures of the urethra J. W. VISHER (*Med. Journ. and Record*, January 21st, 1931, p. 87) recommends the injection of 15 minims of adrenaline added to half an ounce of 4 per cent. novocain solution, some being carefully forced through the strictured area, where it is retained for fifteen minutes. If there has been recent instrumentation, sterile water should be used to dilute the adrenaline, since the novocain may be rapidly absorbed from the damaged surfaces. The urethra is later filled with sterile olive oil, and the penis is raised so that all the oil does not escape. Filiform bougies are now introduced, one after another, and a careful search is made for the opening. Sometimes, if they fail to pass, it is well to depress the penis and to make a fresh attempt, since this may direct them towards the opening in the urethra. The author has found this procedure successful in a large percentage of cases. The adrenaline relieves the oedema and congestion in the strictured area, and greatly facilitates the passage of the bougie.

245 Total Resection of the Stomach

E. BERESOW (*Zentralbl. f. Chir.*, January 31st, 1931, p. 266), who records two personal cases, states that total resection of the stomach was first performed by Schlatter in 1897. In 1927 Uhlhorn was able to collect 30 cases which had ended in recovery. In most of them the Billroth II operation had been performed, since it is an undoubtedly milder operation; it is apparently less dangerous than any other owing to the lesser degree of tension which it entails. The author remarks that, although the first statement is incontestable, there is some doubt as to the truth of the second, since with proper technique the oesophagus and duodenum can be brought together with hardly any tension. Beresow's patients were both operated on by the Billroth I method under local anaesthesia for carcinoma of the stomach. The first was a man, aged 51, whose illness was of ten months' duration; death ensued on the day after operation. The second patient was a man, aged 50, who had been ill for five months; his recovery was uneventful.

246 Adenomatous Goitres

M. SCHTEINGART (*Rev. Sud-Amér. de Méd. et de Chir.*, December, 1930, p. 1193) discusses the different varieties of thyroid enlargements and their corresponding treatments. He rejects the view that all goitres should be operated on without delay, and calls attention to the fact that in some cases the primary cause of the abnormality is to be sought outside the thyroid gland. Radiotherapy and iodine are not necessarily always contraindicated in the case of adenomatous goitre associated with toxaemia; the first form of treatment is, however, unsuitable for adenomatous goitres without hyperthyroidism, and for patients whose metabolism is normal or subnormal. Early operation is required in cases of thyroid enlargement causing respiratory embarrassment, and when large toxic adenomatous growths are associated with symptoms of hyperthyroidism. The author reports observations on 50 cases of non-toxic adenomatous goitre and 125 cases of hyperthyroidism complicating adenomatous enlargement of the thyroid gland.

247 Treatment of Urethral Caruncle

A. G. FLEISCHMAN (*Urol. and Cut. Rev.*, January, 1931, p. 42) states that for a number of years surgical excision has been regarded as the accepted procedure for dealing with urethral caruncle. It presents, however, the following disadvantages: difficulty in checking haemorrhage; development of cicatrices which later become urethral strictures; greater frequency of recurrences; delay in healing of the wound; and predisposition to future urethral deformity. Cauterization by chemical agents or the actual cautery entails similar disadvantages. On the other hand, destruction of caruncles by the high-frequency current, first introduced by Ballenger in 1917, has the disadvantages that there is no haemorrhage nor charring of the tissues, it has deep penetrative properties, and recurrences are few. Urethral deformity is rare. The procedure can be performed under local anaesthesia.

Therapeutics

248 Lipiodol Injections in Neuralgia and Rheumatic Pains

Following Sicard in using local injections of lipiodol for the relief of pain; F. COSTE (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, February 2nd, 1931, p. 103) finds that this drug is harmless to the tissues, and tends to produce circulatory changes modifying pathological processes; although it lacks the immediate anaesthetic effect of novocain the relief induced is more permanent. In some cases the subperiosteal injection of lipiodol, at the point where the sciatic nerve crosses the ischial ramus, appears to cause the rapid breaking down of adhesions. When the seat of trouble is high the paravertebral injection of novocain at the level of the fifth lumbar vertebra often gives good immediate results, which may be maintained by immediately introducing a solution of sodium iodide. Coste tries novocain first, and if the improvement lasts several days he repeats the injection. If it is fleeting, he follows up with 15 c.cm. of lipiodol, given by the low epidural route. Another class of cases, well treated by local injection is the "dry arthritis" group, especially monoarthritic conditions such as the "lipo-arthritis" of Weinenbach and Francon, common in women at the menopause and affecting the knee-joint. Sicard injects lipiodol subperiosteally at the inner aspect of the upper tibial surface to infiltrate the peri-articular tissues; intra-articular injection is to be avoided, since it does no good, and often causes painful inflammatory reactions. Coste remarks that this method has proved less successful in "morbus coxae senilis," in which condition radiant heat is still the treatment of choice. In lipo-arthritis of the knee, however, the injection of lipiodol has given far better results.

249 Treatment of Uraemia by X Rays and Thyroxine

Several observers have recorded a diuretic effect from radiation of the kidney by *x* rays, and A. H. MÜLLER (*Deut. med. Woch.*, February 6th, 1931, p. 230) describes two cases of uraemia which were treated by a combination of *x*-ray and thyroid therapy with good results. The first case was one of arterio-sclerotic kidney with pre-uraemic symptoms, in which diuresis, with improvement in subjective symptoms, occurred nine days after treatment was commenced. The non-protein nitrogen of the blood sank from 100 to 40 mg. per 100 c.cm., and the patient was later discharged much improved. The second case—subchronic glomerulonephritis becoming uraemic (non-protein nitrogen, 97 mg.)—showed a diuresis with diminution of oedema in seven days, and the patient was discharged without oedema or uraemic symptoms. Six months later he showed no fresh signs of renal failure, though albuminuria continued. Both patients had previously failed to respond to the usual dietetic treatment.

250 Administration of Iron

S. R. METTIER and G. R. MINOT (*Amer. Journ. Med. Sci.*, January, 1931, p. 25) report 10 cases of secondary anaemia associated with defective diet or chronic blood loss which responded well to iron therapy. The daily administration of iron was: (1) small doses with an acid beefsteak meal; (2) small doses with an alkaline beefsteak followed (3) by a fourfold to twelvefold increase in the dose of iron. The reticulocyte response following each of these procedures was recorded. The meat had no demonstrable effect on blood formation, and was used only as a medium to maintain the *p*H of the upper gastrointestinal contents approximately constant. The response of the bone marrow to (1) was slightly less than to (2), and it was concluded (particularly because the same dose of iron administered with meat at acid *p*H caused a prompt second response of reticulocytes) that iron is more potent for blood formation when absorbed from an acid than from an alkaline medium. The response induced by procedure (3) indicated that the small dose was not optimum, and emphasized the importance of giving full doses of iron to anaemic patients.

Dermatology

251 Yeast Factors in Superficial Dermatitis

S. W. BECKER and E. B. RITCHIE (*Arch. Derm. and Syph.*, November, 1930, p. 790) believe that fungous infections are more common now, and are recognized more frequently. Several dermatoses of unknown origin yield fungi on culture, and it is uncertain whether these are causal agents or secondary invaders. The presence of hyphae denotes fungous infection of which antecedent (plantar) dysidrosis or intertrigo may be a predisposing cause. Cryptococci have been found in seborrhoeic dermatitis and infantile eczema, while these organisms and yeasts have been obtained from various forms of intertrigo as the result of macerating epidermal scales or scrapings in an aqueous solution of caustic potash, followed by subculture. The present authors conclude that while thrush is due probably to the *Oïdium albicans*, interdigital and genital erosions offer a soil favourable to other organisms. Oïdium was found in all cases of blastomycetic interdigital erosion; *Monilia* and hyphal forms have been found in the same interdigital space. Several cases of genital thrush occurred in diabetic women, but it is not confined to that sex. The authors regard oïdium as causative because it is so constantly present in thrush, and parasiticide treatment is quickly curative while soothing and protective applications are not. Other organisms do not react so readily to parasiticides. The so-called mosaic fungus is, they find, really a collection of organic material, possibly derived from inflammatory dermal changes. Caution is advised in attributing pathogenicity on insufficient evidence.

252 Cutis Marmorata (Livedo Reticularis)

N. E. ARONSTAM (*Urol. and Cut. Rev.*, December, 1930, p. 813), who records an illustrative case, states that this condition, which is also known as cutis marmorata or marble skin, consists in a mottling or speckling of the skin in grotesque reticulated formations, bearing a violaceous or dusky marbling almost bordering on the livid. Its configuration resembles serpentine segments of circles, semicircles, and triangles, occasionally relieved by annular or circinate figures. It occurs as a rule in young people, very rarely during middle age, and is extremely rare in senescence. Aronstam's patients were mainly girls at the age of puberty, in whom it constitutes a source of physical and mental annoyance. Livedo reticularis has been found associated with hepatic cirrhosis, varicosities, erysipelas, colds and arthritic conditions, congenital myxoedema, mongolian idiocy, syphilis, tuberculosis, and scrofula. Alcoholism and rickets have also been regarded as probable etiological factors. Aronstam suggests that the condition is due to hormonic deficiency, since in the majority of cases it appears in girls at the onset of puberty. Pathologically, as Renaut has shown, livedo is the result of the tuft-like arrangements of the blood vessels distributed throughout the affected parts.

253 Heredity in Psoriasis

H. D. NILES (*Med. Journ. and Record*, January 21st, 1931, p. 80) denies that psoriasis is a congenital disease in the ordinary sense of the term, but agrees that it depends on an inherited diathesis, though this is associated with an exciting cause. The incidence of the condition is definitely higher in psoriatic families than in the remainder of the population. He found that the familial incidence in a series of 286 private patients was 23.8 per cent., and in 13.28 per cent. of these a parent, grandparent, or child was affected. The familial incidence in 23 clinic patients was, however, 9.5 per cent., and none of the parents was affected. Niles attributes this discrepancy to the lack of knowledge about their parents shown by his clinic patients, many of whom were of foreign ancestry. He comments on the difference of opinion among authorities as to the inheritability or otherwise of this disease, and adds that in so common a skin affection (4 per cent. of all dermatoses) it is not surprising to find it occurring frequently among the relatives of psoriatics.

Obstetrics and Gynaecology

254 Conservative Operation for Adnexal Inflammation

P. MALCOVATI (*Ann. Ostet. e Ginecol.*, December, 1930, p. 1206) describes favourable results in 52 cases of chronic or latent adnexal inflammation treated under Alfieri's direction by laparotomy, conservation of the whole or occasionally a portion of the uterus, and excision of one or both tubes and/or one or both ovaries. Six cases are included in which salpingostomatoplasty was performed on one or both sides; in two of these the patient subsequently became pregnant. The inflammation was tuberculous in 7, gonorrhoeal in 12, septic in 21, and of doubtful cause in 12. A Mikulicz drain was used after eight of the operations. No deaths occurred, and cure was complete in nine out of ten, the menstrual function being retained; it became regular in over one-half of the cases. Those who after the operation were left with a possibility of conception numbered twenty-four; of these (after one to seven years) five became pregnant and went to term, and one had an abortion. Two of these six conceptions were in patients sterile before operation; these were cases of marital gonorrhoeal infection, in which surgical treatment had not been unduly delayed. Of six cases in which both tubes, and both ovaries excepting a minute fragment, were excised, menstruation continued in two.

255 Cervical Lacerations

W. H. EMRICH (*Amer. Journ. of Surg.*, December, 1930, p. 557) advises the immediate repair of the post-partum cervix as a routine procedure, in order to prevent subsequent chronic ill-health. He describes the use in this connexion of a specially designed vaginal speculum and retractor, which enables good vision of the cervix to be easily obtained. If the cervical tears are bleeding profusely, a suction pump is used until the haemorrhage can be controlled by suture. The cervix is picked up by sponge forceps and its circumference carefully examined, lacerations being closed by interrupted "through-and through" sutures of No. 4 forty-day chromic catgut from their extremities to the os. The anterior and posterior lips are closely approximated, but no sutures are drawn tight. An iodoform gauze strip is retained for twenty-four hours in contact with the cervix; ergot is administered to prevent clot formation and the consequent tearing out of the sutures. Emrich claims that this procedure diminishes the post-partum discharge, shortens convalescence, reduces the liability to leucorrhoeal conditions, and may be considered as a preventive of subsequent malignant development.

256 Treatment of Abortion

In the opinion of T. V. PEARCE (*Journ. Obstet. and Gynaecol. of the British Empire*, Winter, 1930, p. 769) the best treatment of abortion consists in early and gentle evacuation of the uterus, and haemorrhage and sepsis are cardinal indications for this. Each manipulation of a potentially infected uterus after abortion must be regarded as amounting probably to inoculation with living organisms, and any pelvic examination or treatment must therefore be conducted with the utmost gentleness. The first step in treatment consists in intrauterine douching with hot eusol. In emptying the uterus subsequently digital instead of instrumental dilatation of the cervix often suffices; removal of foetal and placental remnants, located by the finger, is best effected with ovum forceps. The administration of morphine will often render a general anaesthetic unnecessary. To empty the uterus is more urgent in haemorrhage than in sepsis. Ecbolic drugs are uncertain in their action on the uterus after an abortion, and before term such a uterus does not respond readily to the intramuscular injection of pituitary extract, even in large doses. The author has, however, found that haemorrhage is controlled immediately by the direct injection of pituitary extract into the fundus uteri; the uterus, which must be known to be empty, is pressed against the suprapubic abdominal wall by one hand in

the vagina, and the needle is thrust into the uterine muscle through the skin and anterior sheath of the rectus. Such administration of pituitary extract renders it unnecessary to pack the uterus or vagina for haemorrhage.

257 Eclampsia in China

G. KING (*Nat. Med. Journ. of China*, December, 1930, p. 653) believes that the incidence of eclampsia is unduly high in China, and agrees that there is a definite preponderance of cases in the autumn and winter. In a series of 33 cases encountered at the Peking Union Medical College Hospital during the eight years 1922 to 1930, 24 of the patients were primiparae, and the average age was 24. Of the 9 multiparae, 6 had already given birth to upwards of six children each, and 4 of these had had previous toxaemic pregnancies. In only 12 per cent. of the cases had there been ante-natal care, and in these no deaths occurred. The importance of regular ante-natal examination of the urine and blood pressure is emphasized. The eclamptic symptoms appeared before labour in 60 per cent. of the cases; during labour in 30 per cent.; and after labour in 10 per cent. Definite changes in the ocular fundus were detected in the majority. Conservative treatment, based upon Stroganoff's method, is favoured by the author, Caesarean section being employed only in exceptional cases.

258 Gonorrhoea of the Rectum

According to N. TEMESVÁRY (*Zentralbl. f. Gynäk.*, December 13th, 1930, p. 3140) gonorrhoea of the rectum was found in one in five women (prostitutes excluded) admitted to hospital for gonorrhoea. Of 261 cases, in 88 the first microscopical examinations, in 70 the second or third, in 55 the fourth to seventh, and in the remainder the eighth to eighteenth revealed the gonococcus in the rectum. Only 5 per cent. had symptoms pointing to affection of the rectum, and gross rectal objective signs were present in but four patients. Treatment, continued conscientiously for an average period of 45 days, is almost certain to be successful. In the morning, after stool, 125 grams of a 2 in 1,000 trypaflavine solution are introduced into the rectum; at night there is injected through a suitable syringe silver nitrate 1 gram, balsam of Peru 10 grams, and yellow vaseline to 100 grams.

Pathology

259 Immunization against Vaccinia by Virus-Serum Mixtures

C. P. RHOADS (*Journ. Exper. Med.*, February, 1931, p. 185) describes the successful immunization of rabbits against vaccinia by the inoculation of neutral mixtures of virus and immune serum. The virus used was a strain of neurovaccine, kept potent by fairly frequent animal passage; it was maintained in the form of a 10 per cent. suspension of rabbit brain. An immune serum was prepared by bleeding rabbits three weeks after recovery from acute pustular vaccinia. In most instances 0.2 c.cm. of serum sufficed to inactivate an equal amount of a 1 in 100 dilution of a virus which gave rise to lesions in a dilution of 1 in 100,000. For purposes of vaccination a 1 in 200 dilution of virus was mixed with immune serum, and the mixture, which gave rise to no reaction when injected intradermally in rabbits, was either instilled into the nose or inoculated subcutaneously. The nasal instillations were given at one-day or two-day intervals until three to five doses had been applied; in the subcutaneous series three injections were given of 2 c.cm. at intervals of four days. Six weeks after the last inoculation the rabbits were tested for immunity by the intradermal inoculation of graded doses of virus. The results showed that, provided the serum was neither under- nor over-neutralized, the virus-serum mixtures produced a satisfactory immunity response. If an excess of serum was present the resulting immunity was slight; if insufficient serum was used, a typically delayed vaccinia lesion appeared when the mixture was inoculated intradermally into a control animal. By suitable mixtures the author has therefore produced immunity in rabbits with no local lesion and only a minimum systemic reaction.

260 Serum Reactions in Carcinoma

O. SIEVERS (*Finska Läkaresällsk. Handlingar*, January, 1931, p. 7) has carried out at the Sero-Bacteriological Laboratory of the University in Helsingfors investigations into the specificity of Hirszfeld's complement-fixation test and Kahn's albumin-A test in relation to carcinoma. In 46.8 per cent. of 62 cases of carcinoma a positive reaction was obtained to Hirszfield's complement-fixation test, which was performed altogether on 296 serums. The reaction was usually negative in those cases in which the carcinoma was of recent origin or superficially situated. It was also negative, as a rule, when the diagnosis of carcinoma was uncertain and in the presence of other types of new growth. In all the 25 Wassermann-positive serums examined the carcinoma reaction was also positive. In certain other cases, with a negative Wassermann reaction but with a history of syphilis, a positive carcinoma reaction was obtained. This reaction was positive, however, in only 10.7 per cent. of the non-syphilitic controls. Kahn's albumin-A reaction was investigated in 341 serums, and was found to be positive in 80.8 per cent. of the cases associated with new growths. When the tumours were small or superficial this reaction was usually negative. Repetitions of the test, when a positive reaction had been obtained to the serum of a tumour case, continued to be consistently positive. Among 233 control cases without new growths, positive reactions were obtained in 30 per cent.; and when some of these tests were repeated the reaction was sometimes negative. Sievers concludes that an albumin-A reaction, which is sometimes positive and sometimes negative in the same case, is suggestive of the absence of a new growth.

261 Etiology of Psittacosis

G. EIGLER (*Zentralbl. f. Bakt.*, February 3rd, 1931, p. 406) describes the finding of a tiny Gram-negative influenza-like cocco-bacillus in the sputum of nineteen patients suffering from psittacosis and in two parrots. During the height of the disease this organism was present in enormous numbers in the sputum, and could be cultivated on blood agar; during convalescence, though it was found in some patients in large numbers, mostly intracellularly, it could not be recovered in culture. The organism would grow only on media containing blood; blood agar and Levinthal's medium were found the most satisfactory. For isolation, blood agar plates were best; on this medium the colonies after twenty-four hours appeared as clear transparent droplets 0.5 mm. in diameter; after two or three days they increased in size, became flatter, and took on a greenish tinge. Injection of parrots with pure cultures of this organism, even in small doses such as 1/100 of a loopful, gave rise as a rule to a fatal disease resembling natural psittacosis. Of great interest was the discovery that pure cultures were able to pass through Berkefeld V and N candles, though not through W candles. In the author's opinion this observation may help to bridge the gap between his findings and those of the English workers who believe that psittacosis is due to a filterable virus.

262 The Bactericidal Power of the Blood in Alcoholism

S. SEGRE and A. ANGYAL (*Giorn. di Batteriol. e Immunol.*, January, 1931, p. 80) examined the bactericidal power of the whole blood and plasma on *B. typhosus* and the cholera vibrio both in normal persons and in alcoholic subjects, and found that the latter showed a marked diminution of this power without there being any numerical change in the leucocyte count. The alcoholic subjects were inmates of an asylum and were mostly suffering from confusional states, hallucinatory psychoses, and tremors, while the controls, though not complete abstainers, were very moderate in their use of alcoholic beverages.

IODINE AND BROMINE DERIVATIVES OF ASPIRIN

With regard to the article in last week's *British Medical Journal* (p. 383), on "The Medicinal Treatment of Chronic Arthritis," we wish to point out that:

"ASPRIODINE" - - - contains over **41% of Iodine,** the balance being the Aspirin radical.

"SEDASPRIN" - - - contains over **30% of Bromine,** the balance being the Aspirin radical.

"METHYL-ASPRIODINE" contains over **39% of Iodine,** and the acidic radical is not Salicylic, but is the Aspirin radical.

It will be seen therefore that "Aspriodine" and "Sedasprin" are not the same chemically as Aspirin, nor is "Methyl-Aspriodine" an equivalent to Methyl Salicylate.

Please write for particulars of these and other Martindale preparations.

TUBERCULOSIS...
"A disease of houses"

Tuberculosis has been well described as "a disease of houses." Although we cannot hope to cure individual cases of tuberculosis by making our houses healthier we can do much to *prevent* this dread disease by admitting fresh air and "whole" daylight into every kind of building where people live and work indoors.

"Vita" Glass offers the simplest and most practicable means of bringing the ultra-violet rays to indoor workers. Its permanence is guaranteed and the new stabilised prices, from 1/- per square foot, make its cost reasonable whether recommended by the general practitioner for private patients or by the medical officer for buildings under his control.

Write for further particulars to the "Vita" Glass Marketing Board, 9, Crown Works, St. Helens, Lancashire.

"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers and Builders.

"VITA" GLASS

"Vita" is the registered Trade Mark of Pilkington Brothers Limited, St. Helens

DEAF DOCTORS
AND DEAF PATIENTS

have proved "ARDENTE" a boon—a Heart Specialist whose work is so dependent on his hearing writes: *"'Ardente' is a godsend to me"*; without "ARDENTE" he is, to all intents and purposes, "stone" deaf; with "ARDENTE" he carries on his work—what better testimony to "ARDENTE" merit?

Mr. Dent makes a Stethoscope specially for deaf Doctors—the only one of its kind, which is widely used and praised. Doctors whose work lies amongst the deaf prefer to prescribe "ARDENTE" because they know that "ARDENTE" is the only individual method in the whole deaf world (no mass production way can ever succeed with human disabilities) and they know what "ARDENTE" service stands for to the deaf. Many doctors who are deaf use "ARDENTE."

"ARDENTE" is entirely different and uncopyable and succeeds in widely differing cases. A full range covers the needs of those suffering from varying forms and degrees of deafness and tinnitus. Minutely adjusted to the requirements of the case for young, middle-aged, or old, and so sensitive as to have the desired effect even in middle-ear and nerve cases, bringing into action and stimulating the auditory system, enabling it to function naturally and saving atrophy. "ARDENTE" can be used or not at will, and is sold under guarantee.

"ARDENTE" is the choice of Doctor and patient—only after test and hearing, or from prescription or particulars, is "ARDENTE" fitted, toned, tried, adjusted, supplied, and serviced.

Tests and demonstrations given at Doctors', patients' or our addresses, without fee or obligation.

MR R.H.DENT'S **ArdenTE** FOR DEAF EARS

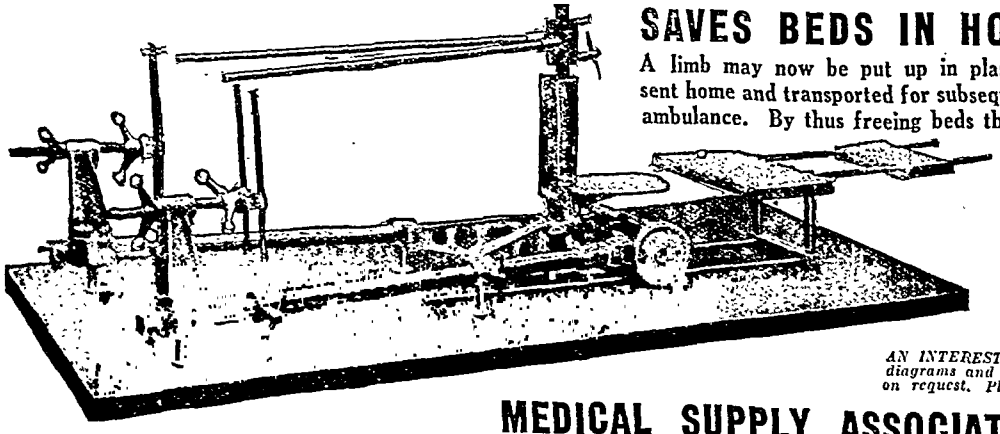
An IMPROVED and MODIFIED
Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35 in. × 15 in. × 11 in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy.

STANIFORM

Regd. BRAND. Trade Mark.

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds, etc.

DUSTING POWDER
For application where a greasy substance is contra-indicated.

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis.

LOTION
A anacea for Mosquito and other insect bites. Most effective for all purposes where Tr. Iodine is employed. Does not stain the skin and there is no sting.

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies.

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical Men:

"I have treated with 'Staniform' a very bad scald of chest in a child, who had boiling water spilt over her. It healed completely in fourteen days without a scar."

"I have tried 'Staniform' in the Out-patients' Department and both Nursing Staff and myself were amazed at results obtained. Long-standing, non-healing skin wounds healed after few applications."

"This is to certify that 'Staniform' has been used with great success in the Emma-Klinick (Utrecht, Holland), in cases of bed-sores, in burns of heat and X-rays."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties. Combining the well-known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing.

STANIFORM LTD., CARNWATH ROAD, LONDON, S.W.6

Vapo-Cresolene
Est. 1879
Sold by all Chemists

Write for descriptive Booklet No. 29.

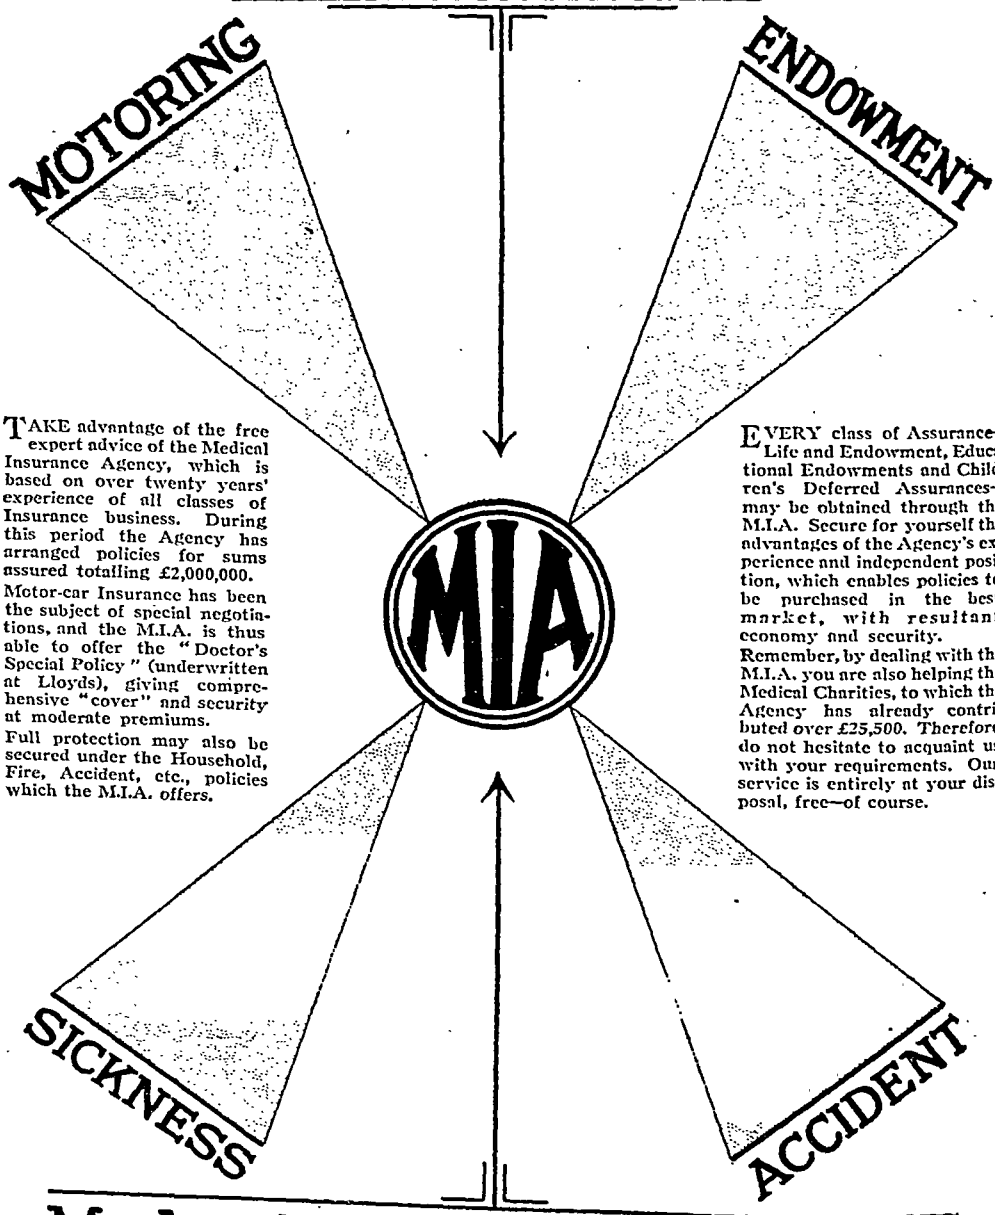
ALLEN & HANBURYS, LTD. :: :: Lombard Street, London, E.C.3.

ASTHMA

There are certain types of chronic asthmatics who require relief of their paroxysms. While adrenaline is generally effective, it must be given hypodermically, and its action is short lived. Vapo-Cresolene (specially prepared cresols of coal tar) vaporized in the bedroom at night will give the desired relief. The patient is not disturbed as he breathes the medicated air of the bedroom.

This antiseptic vapour is particularly effective in bronchial ailments accompanied with cough and difficult breathing—as bronchitis, whooping cough, spasmodic croup.

Insurance



TAKE advantage of the free expert advice of the Medical Insurance Agency, which is based on over twenty years' experience of all classes of Insurance business. During this period the Agency has arranged policies for sums assured totalling £2,000,000.

Motor-car Insurance has been the subject of special negotiations, and the M.I.A. is thus able to offer the "Doctor's Special Policy" (underwritten at Lloyds), giving comprehensive "cover" and security at moderate premiums.

Full protection may also be secured under the Household, Fire, Accident, etc., policies which the M.I.A. offers.

EVERY class of Assurance—Life and Endowment, Educational Endowments and Children's Deferred Assurances—may be obtained through the M.I.A. Secure for yourself the advantages of the Agency's experience and independent position, which enables policies to be purchased in the best market, with resultant economy and security.

Remember, by dealing with the M.I.A. you are also helping the Medical Charities, to which the Agency has already contributed over £25,500. Therefore do not hesitate to acquaint us with your requirements. Our service is entirely at your disposal, free—of course.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and *pathological* examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary *boarders* can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy *Douche, Scotch Douche, Electrical bath, Plombières treatment*, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the *Hospital from the farm*, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully *situated in a Park* of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. *Voluntary Boarders or Patients* may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there *are cricket grounds*, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf-courses, and bowling greens. Ladies and gentlemen have their own gardens, and *facilities are provided* for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders,

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: Bethlem, Beckenham. *Telephone*: Springpark 1180—1181.

Station: Eden Park (Southern Railway).

President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital.

RUTHIN CASTLE

ITALIAN HEALTH RESORTS

IN WINTER AND EARLY SPRING there are, in Italy, more SUNNY and WARM RESORTS and SPAS than in any other country in Europe. Many of them have the best all-round climatic conditions to be found in Europe.

IN SUMMER AND AUTUMN. The greater part of Italy is more pleasant in Summer than at any other Season of the year. There are HUNDREDS of DELIGHTFUL ALPINE, DOLOMITE, LAKE and SEA-SIDE RESORTS.

THE SPAS OF ITALY are world famous for their 'cures,' and besides those having seasons in the Spring, Summer, and Autumn there are many that have a pleasant Winter climate.

ENIT ALL THE YEAR ROUND ENIT

Resident Assistant Physician: N. R. WYNN WILLIAMS, M.B., B.S.(Lond.), formerly House Physician to the Brompton Chest Hospital, London; and Medical Registrar to the Middlesex Hospital.

THE TREATMENT OF RHEUMATOID ARTHRITIS

THIS disease, which the medical man is increasingly called upon to combat, may be successfully treated by the correct application of Pistany radio-active Mud Packs.

The packs can be applied in the patient's own home if necessary, and the treatment may be successfully combined with other physio-therapeutic methods.

Pistany (Czecho-Slovakia) offers the most effective treatment for the cure of rheumatoid arthritis. The properties of Pistany's hot volcanic soft mud are quite peculiar. During the season over 26,000 visitors go to this picturesque Spa, and statistics show that of 100% of patients, only less than 5% do not respond to the treatment—30% are completely relieved and 65% are considerably improved. Home treatment can never supersede the cure at the Spa.

Canvassing, either directly or indirectly, will disqualify a candidate.

FRANK H. WORSLEY, Town Clerk.

City of Manchester.

PUBLIC HEALTH DEPARTMENT.

WITHINGTON HOSPITAL.

APPOINTMENT OF AN ASSISTANT MEDICAL OFFICER.

The Public Health Committee invites applications from qualified Medical Men for the position of Assistant Medical Officer at the Withington Hospital (1,200 beds) and Institution (1,150 beds), Nell Lane, West Didsbury, Manchester.

The successful candidate will be required to have the care of the wards for patients suffering from Pulmonary Tuberculosis (150 Beds).

Every applicant must be a registered Medical Practitioner and unmarried.

Preference will be given to applicants with previous hospital experience.

The Hospital is a recognised Training School for Nurses and is equipped with all modern requirements.

Salary £350 per annum, with board, residence, and laundry in addition. No bonus.

The appointment will be made in the first instance for a period of six months, renewable at the end of that period for a further six months.

Every application, stating fully the training, qualifications, and experience of the candidate, and his age, with copies of three recent testimonials, and endorsed on the envelope "Assistant Medical Officer, Withington Hospital," must be addressed to the Medical Officer of Health, Civic Buildings, 1, Mount Street, Manchester, only, and not to members of the Committee or Council, and must be received by him not later than Thursday, March 19th.

The candidate appointed will be required to commence duty as soon as possible after appointment, to devote the whole of his time to the duties of the position, to pass a medical examination, to contribute to the Corporation Superannuation Fund, and to execute the Deed of Service.

Canvassing in any form, oral or written, direct or indirect, is prohibited.

Town Hall, Manchester. F. E. WARBRECK HOWELL, Town Clerk.

March 2nd, 1931.

City of Manchester.

MONSALL HOSPITAL FOR INFECTIOUS DISEASES. (600 Beds.)

APPOINTMENT OF JUNIOR MEDICAL OFFICER.

The Public Health Committee invites applications from qualified Medical Men for the position of Junior Medical Officer at Monsall Hospital.

Every applicant must be a registered Medical Practitioner and unmarried.

Preference will be given to applicants who have held Resident Surgical and Medical posts in a General Hospital.

The candidate appointed will be required to assist in the teaching of the nursing staff and to reside at the Hospital.

Salary £350 per annum, with board, residence, and laundry in addition. No bonus.

The appointment will be made in the first instance for a period of six months, renewable at the end of that period for a further six months.

Every application, stating fully the training, qualifications, and experience of the candidate, and his age, with copies of three recent testimonials, and endorsed on the envelope "Junior Medical Officer, Monsall Hospital," must be addressed to the Medical Officer of Health, Civic Buildings, 1, Mount Street, Manchester, only, and not to members of the Committee or Council, and must be received by him not later than Thursday, March 19th.

The candidate appointed will be required to devote the whole of his time to the duties of the position, to pass a medical examination, to contribute to the Corporation Superannuation Fund, and to execute the Deed of Service.

Canvassing in any form, oral or written, direct, or indirect, is prohibited.

Town Hall, Manchester. F. E. WARBRECK HOWELL, Town Clerk.

March 2nd, 1931.

The Gloucestershire Royal

INFIRMARY AND EYE INSTITUTION, GLOUCESTER.
(153 Beds—4 Residents.)

Applications are invited for the post of FIRST HOUSE SURGEON (male). Salary at the rate of £150 per annum. Six months' appointment, with board, residence, and laundry.

F. J. SYMONS, Secretary.

March 12th, 1931.

Nottinghamshire County Council

MANSFIELD WOODHOUSE URBAN DISTRICT COUNCIL.

APPOINTMENT OF JOINT MEDICAL OFFICER.

The Nottinghamshire County Council and the Mansfield Woodhouse Urban District Council invite applications from duly qualified and registered Medical Practitioners for the joint whole-time appointment of ASSISTANT SCHOOL MEDICAL and DISTRICT MEDICAL OFFICER OF HEALTH.

The salary attaching to the position will be £800 per annum, with reasonable travelling and subsistence allowances.

Applicants must have had experience in the duties of a Medical Officer of Health, and also possess the Diploma in Public Health. Experience in Refraction work and the examination of Mentally Defective Children will be considered an advantage.

The person appointed will be required to reside in the Urban District of Mansfield Woodhouse or within a radius of three miles from the Mansfield Woodhouse Post Office.

As regards his duties under the County Council, the officer will act under the general control and supervision of the County Medical Officer, and will be required to perform such duties, either as School Medical Officer or otherwise, as may be from time to time prescribed.

As regards his duties as District Medical Officer of Health, the officer will also be required to act as Medical Officer for Maternity and Child Welfare in the Urban District, and will be subject to the sole control and direction of the Mansfield Woodhouse Urban District Council.

The appointment will be determinable on three months' notice, and, as far as the office of District Medical Officer is concerned, will be subject to the approval of the Ministry of Health and the provisions of the Sanitary Officers Order, 1926.

Applications, on forms to be obtained from the undersigned, accompanied by copies of not more than three recent testimonials, must reach me not later than Saturday, March 21st.

K. TWEEDALE MEABY, Clerk of the County Council.

Shire Hall, Nottingham.

March 1st, 1931.

HACKNEY HOSPITAL,
High Street, Homerton, E.9.

ASSISTANT MEDICAL OFFICER. — Salary £350 a year, rising by annual increments of £25 to a maximum of £425 a year, together with board, lodging, and washing. Candidates must have held a resident appointment in a General Hospital for at least six months. Preference will be given to a candidate with experience in Midwifery and Gynaecology who is capable of performing operations appertaining to these subjects. There is no accommodation for a married man.

Forms of application may be obtained (stamped addressed foolscap envelope necessary) from the Medical Officer of Health (Staff Division 4a), The County Hall, Westminster Bridge, S.E.1, and must be returned by March 27th. Canvassing disqualifies. Inquiries for further details as to the nature and scope of the duties should be addressed to the Medical Superintendent at the Hospital.

MONTAGU H. COX,
Clerk of the London County Council.

Administrative County of LONDON.

The LONDON COUNTY COUNCIL invites applications from duly qualified Medical Practitioners for a position of DISTRICT MEDICAL OFFICER for the City of London, at a provisional salary of £125 a year. The appointment is a part-time one, and will be made until June 30th in the first instance. The salary is subject to review.

The candidate appointed will be required to reside within the district, and to attend daily at the place appointed by the Council, as well as visit applicants for medical relief at their homes at any hour on receipt of a relieving officer's order. Other duties may be assigned to the position in addition to those ordinarily appertaining thereto.

Forms of application, containing full details, can be obtained from the Medical Officer of Health (5.D4a), The County Hall, Westminster Bridge, S.E.1.

A stamped addressed envelope should be enclosed, and forms of application must be returned by March 24th. Canvassing disqualifies.

MONTAGU H. COX,
Clerk of the London County Council.

TENDERS.

County Council of Middlesex.

PUBLIC ASSISTANCE DEPARTMENT.

TENDERS FOR SUPPLIES.

The Middlesex County Council invite Tenders for the supply of the following Goods or Materials, in each case for a period of six months (except where otherwise stated) from April 1st, to their several Public Assistance Hospitals and Institutions:

DRUGS.
MEDICAL AND SURGICAL APPLIANCES.
DRESSINGS.
SURGICAL INSTRUMENTS.
PATHOLOGICAL SUNDRIES.
RADIOLOGICAL REQUISITES.
RADIUM REQUISITES.
DENTAL REQUISITES.

Forms of Tender (upon which only tenders will be received) and conditions of contract may be obtained on application to the Director of Public Assistance, 10, Great George Street, Westminster, S.W.1, accompanied by a stamped, addressed, foolscap envelope.

Sealed Tenders, marked "Tender for —," must be delivered on or before 11 a.m. on Monday, March 23rd, addressed to "The Clerk of the Middlesex County Council, Guildhall, Westminster, S.W.1."

The Council do not bind themselves to accept the lowest or any Tender, and reserve the right to accept any Tender or part only.

Estimated quantities required are stated in the form of Tender, and Tenderers may tender to supply all or any one or more of the Establishments concerned.

Guildhall, Westminster. March, 1931.
E. S. W. HART, Clerk of the County Council.

LITERARY.

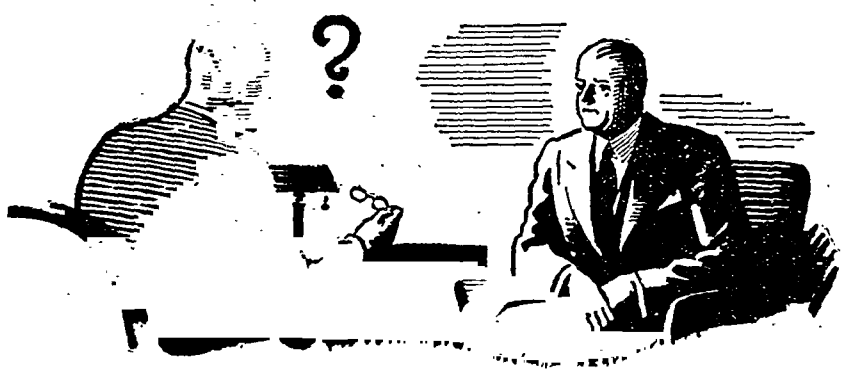
Full Schedule of Terms and Conditions will be forwarded on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.



The Answer to the "first Question"

INVARIABLY before prescribing for any ailment, the first question the physician asks the patient concerns the function of the bowels.

He then naturally asks himself what corrective, if any, to prescribe to suit the condition, without interfering with the treatment.

Agarol provides a safe answer to this.

Agarol Brand Compound the original mineral oil and agar-agar emulsion with phenolphthalein, is free from any artificial flavouring, sugar, alkali or alcohol. It is safe in diabetes, in gastric diseases, for children as well as adults. No excess of mineral oil to interfere with digestion or to cause leakage.

In addition, *gentle stimulation* of peristalsis, makes the result certain and the re-establishment of regular habits possible.

One tablespoonful at bedtime —is the adult dose.

Final decision on the true worth of Agarol Brand Compound rests with the physician. We will gladly send a liberal quantity with literature, for trial.

AGAROL BRAND COMPOUND *for Constipation*

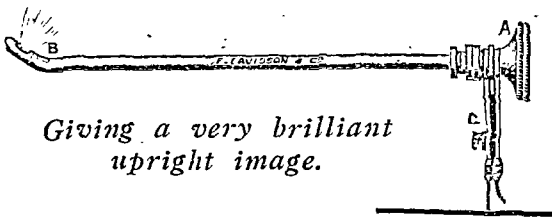
FRANCIS NEWBERY & SONS, LTD., 31-33, Banner Street, London, E.C.1.

Prepared by WILLIAM R. WARNER & CO., INC., *Manufacturing Pharmacists Since 1856.*

High-Grade Examination CYSTOSCOPE

Kollmorgen Optical System.

SPECIAL OFFER—**£6 17 6** WITH SPARE LAMP IN CASE Usual Price 9 Guineas.



Giving a very brilliant upright image.

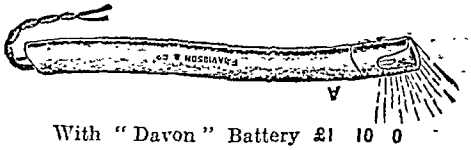
The low price we are able to quote is only possible because we have bought the whole of the large stock of a German manufacturer (in liquidation).

Complete Outfit for Eye, Ear, Nose, and Throat Examination, Transillumination and Light Cautery.

No. 54.	Price	£11 15 0
Ditto without cautery		£9 14 0
Other Outfits from		£3 12 6

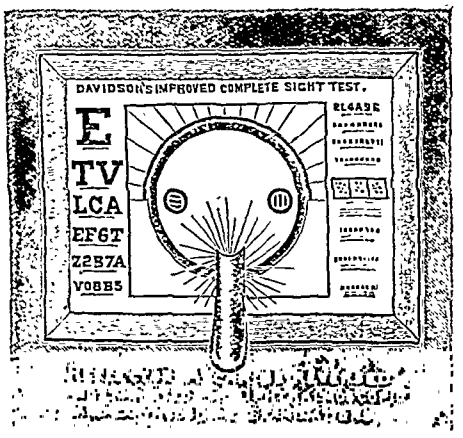
Our "Davon" Battery has been before the profession for over 20 years and maintains its reputation. Many Doctors have used one for 2 years and more. *INSIST UPON HAVING THE "DAVON"* (our registered trade mark) *WITH OUR GUARANTEE BEHIND IT.*

THE "DAVON" SPATULA AND TRANSILLUMINATOR.



With "Davon" Battery £1 10 0

"PARAGON" ILLUMINATED TYPES.



Can be hung on wall, or stood on a shelf or table.

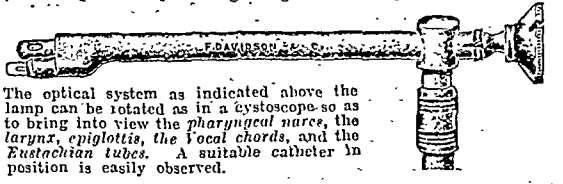
By means of an ingenious arrangement of the light and mirrors, the most brilliant illumination possible is obtained with an ordinary lamp. A metal chimney, asbestos lined, with ground glass shade (for light) and shutter (for reducing the size of illumination) is supplied for Ophthalmoscopic or Laryngoscopic examinations. (Size 18in. × 18in. × 4in.)

Price complete (without bulb) or with Incandescent Gas Burner £3 10 0. Two Sets of Snellen's Types instead of "Complete" Sight Test Card if desired.

ELECTRIC PHARYNGOSCOPE.

(Foreign)

(New Optical System giving much improved view.)



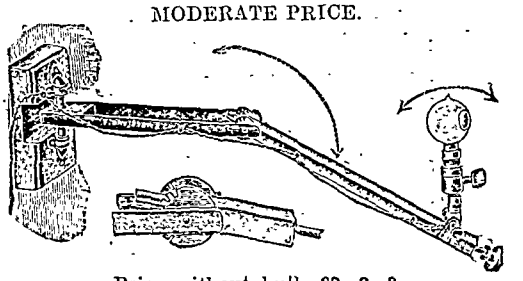
The optical system as indicated above the lamp can be rotated as in a cystoscope so as to bring into view the *pharyngeal nares*, the *larynx*, *epiglottis*, *the Vocal chords*, and the *Eustachian tubes*. A suitable catheter in position is easily observed.

PRICE £5 15 0; in Walnut Box £6 5 0

With "Davon" Battery and Rheostat, contained in Walnut Box, £7 5 6.

THE "DAVON" BRACKET.

Well made and serviceable at a very MODERATE PRICE.



Price without bulb £2 2 0.

Target frosted bulbs (please state voltage) each 3/6.

OCULIST'S TRIAL CASES.

In large variety from £10 10 0 complete. All lenses mounted, and adjustable trial frame. Secondhand cases frequently in stock at tempting prices.

TEST TYPES, &c., of every description.

SEND US YOUR OPTICAL PRESCRIPTIONS. SATISFACTION GUARANTEED and NO FANCY PRICES.

WITH SUPPLEMENT

No. 3663 SATURDAY, MARCH 21, 1931 Price 1/3

PARKE, DAVIS & Co.

PILULA CHOLELITHICA,

(CHOLELITH PILL)

Chocolate-coated pills each containing :—

Acid Sodium Oleate	*1-1/2 grs.*
Sodium Salicylate (Natural)	*1-1/2 grs.*
Phenolphthalein	*1/3 gr.*
Menthol	*1/10 gr.*

A soft-mass pill, consequently there is prompt disintegration in the digestive tract.

Stimulates the secretion of bile and overcomes hepatic torpidity.

Has a laxative effect that is not griping.

Exerts an antiseptic influence on the gall-bladder. (An important point, as infectious processes are frequently a predisposing cause of gall-stones).

Indicated also in inflammations of the gall-bladder not due to the presence of stone.

Has given relief in cases not accurately diagnosed but pointing to gall-bladder and ducts by the presence of pain and tenderness.

Supplied in bottles of 25, 100 and 500. The usual dose is 1 to 4 pills. Further particulars will be sent on request.

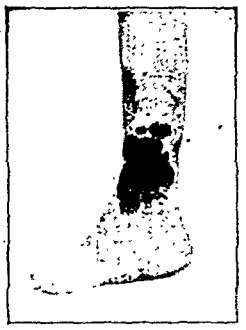
T. J. SMITH & NEPHEW LTD. (Dept. BM),
Surgical Dressings Manufacturers,
HULL, LONDON, MANCHESTER, GLASGOW.

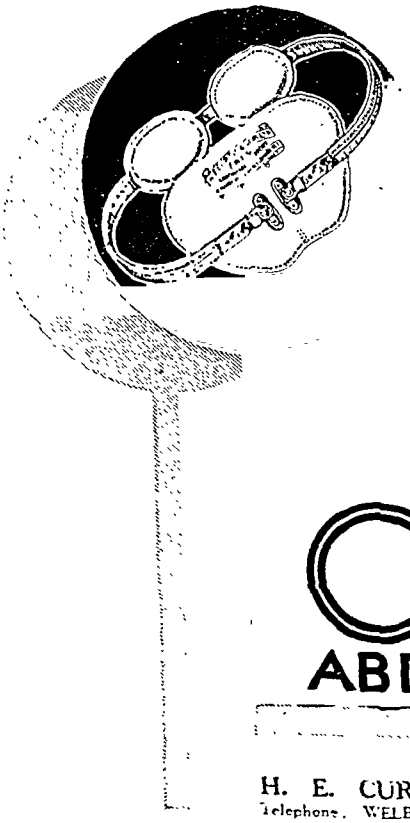
London Office: 42, TAVISTOCK SQ., W.C.1.

Obtainable through all Surgical Supply Houses.



Photograph shows Ulcer of 25 years' duration. Woman patient. Age 63.

After 18 weeks ambulatory treatment with Elastoplast applications. Bandages used—15.



Comfortable, and Correct Support

Assured to all sufferers from abdominal ptosis who wear the Curtis Abdominal Support, Model No. 1. The principle of this support—that of anterior posterior support—has been proved by scientific research to be the most efficient. There is no circumferential pressure, hence the wearer's freedom of movement is in no way restricted. There is no cramping or binding of the hips. It is light in weight, and easy to apply. There are no complicated fastenings.

IN USE IN MOST OF THE LONDON HOSPITALS.

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

Extract from the "British Medical Journal," Dec. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health . . . and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition. . . . Madame Rose has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

ORAL SEPSIS.

"EUMENTHOL JUJUBES" (HUDSON)

Made in Australia.

HARMFUL THROAT TABLETS. Throat Tablets and Lozenges containing Formalin (Formaldehyde) are harmful. Wiley, of the United States, investigated the effects of small doses of Formalin (Formaldehyde) given with milk, on 12 men during 15 days. Burning in the throat, itching, rash, and loss of body weight were observed.—*Vide* Martindale. All countries which have made legal enactments and laws regarding the purity of its food supply have prohibited the addition of Formaldehyde (Formalin) as a preservative of food. HUDSON'S EUMENTHOL JUJUBES contain no Formalin, Cocaine, or other harmful or poisonous drug. Sold everywhere.

THE THEORY OF OBSTETRICS

A Functional Study of Child-bearing based on a new definition of Normal Labour and on a new theory of Uterine Inertia, and Illustrated by a Detailed Statistical Analysis of 100 consecutive Labours, and some Records of Cases of Painless Labour.

By M. C. DE GARIS, M.D., Author of "Clinical Notes and Deductions of a Peripatetic."

¶ *"It constitutes a valuable contribution to the literature on the subject. It cannot be ignored."*—MEDICAL TIMES.

Size 5½ × 8½. Pp. × 11 + 272. Price 12s. 6d. Postage 6d.; Abroad 8d.

BRIGHT'S DISEASE

Observations on the Courses of Different Types and on the Resultant Changes in Renal Anatomy

BY A GROUP FROM THE HOSPITAL OF THE ROCKEFELLER INSTITUTE FOR MEDICAL RESEARCH.

¶ *This work presents a series of cases closely observed over periods varying from weeks to years. The data are presented with the hope of adding to the clarity and completeness with which the variable courses of the different types of renal disease can be recognized.*

Size 6 × 9. Pp. 150. With 4 Colour Plates, 36 Half Tones and 66 Charts. Price 13s. 6d. Postage 6d.

¶ *Deals with almost every possible kind of fracture.*

FRACTURES AND THEIR COMPLICATIONS

By G. E. WILSON, M.B., F.R.C.S., Surgeon-in-Chief, St. Michael's Hospital, Toronto; Assistant Professor of Surgery, University of Toronto; formerly Surgeon in Charge of Emergency and Out-patient Department, Toronto General Hospital.

Size 6 × 9½. Pp. viii + 415. With 306 Illustrations. Price 35s. Postage: Inland, 9d.; Abroad, 1s.

THE FACTOR OF INFECTION IN THE RHEUMATIC STATE

By ALVIN F. COBURN, Resident Physician of the Presbyterian Hospital, New York City.

¶ *The purpose of this study is to present a comprehensive description of the rheumatic state in its many phases, to give a clear conception of the disease picture, and to show the role played by the infectious agent.*

Size 7 × 9½. Pp. ix + 288. With 3 Coloured Plates and 48 other Illustrations. Price 27s. Postage 9d.

BIOASSAYS: A Handbook of Quantitative Pharmacology

By JAMES C. MUNCH, Director of Pharmacological Research, Sharp and Dohme; Pharmacologist, Bureau of Biological Survey, U.S. Department of Agriculture.

¶ *"The first critical comprehensive compilation of the widely scattered and voluminous literature on quantitative pharmacology. It contains a great deal of valuable information."*

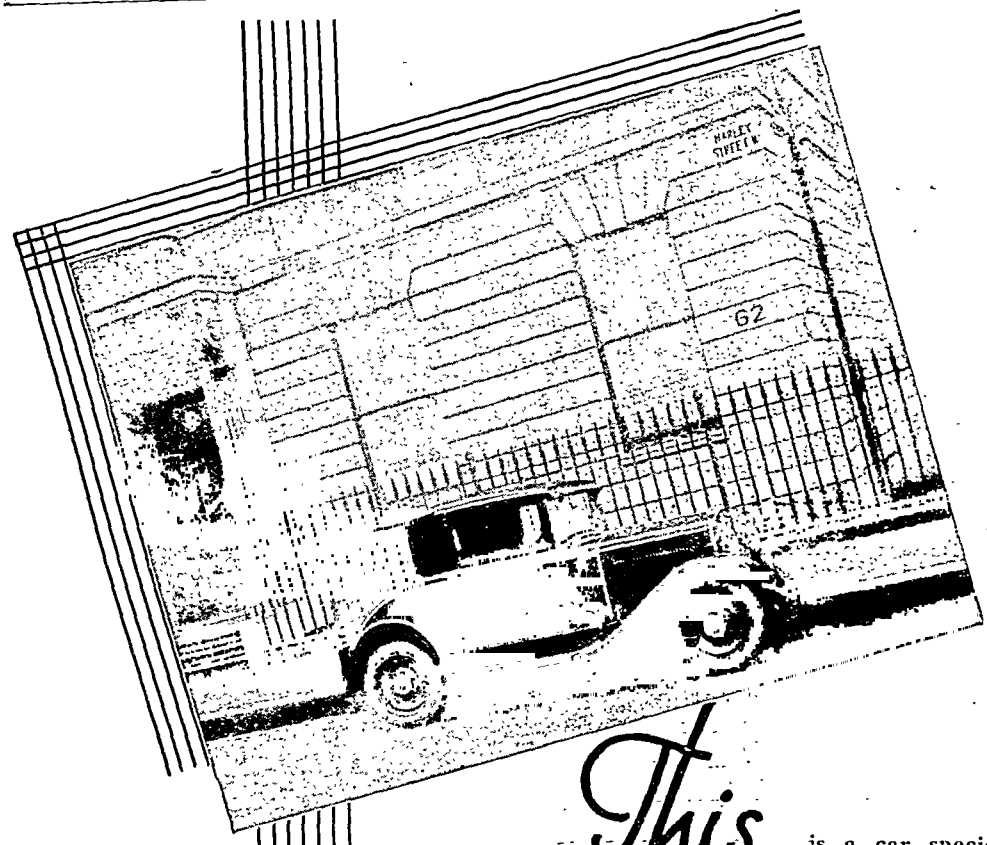
Price 3s. 6d. Postage 4d.

BAILLIÈRE, TINDALL & COX, 7 & 8, Henrietta Street, London, W.C.2



THE FIAT
10/30 RANGE
Two Seater £220
Torpedo - £225
Saloon - - £250
Coupe (as illustrated)

£250

This is a car specially designed to meet the needs of the Medical Profession.

It is compact, sturdy, flexible and reliable —an ideal car for general purposes or for exclusively professional use.

Its size makes it easy to park where a larger car would be inconvenient. At the same time it is undeniably roomy and comfortable.

It is fitted with an oversize 100 amp. battery, which guarantees electric power for lighting and starting no matter how much the car may be used for short journeys or during dark hours. Anti-theft lock as standard.

True to Fiat traditions, the 514 Coupe will stand up to constant use under most trying conditions; and built as it is to cope with the roughest Continental roads and mountain districts, it will prove itself a useful adjunct to any Continental holiday.

FIAT

May we quote you for your car in exchange?

FIAT LONDON DISTRIBUTORS Ltd.
43/44, Albemarle Street, London, W.1
(Phone GERRARD 7946)
New London Service Station and Repair Works:
FARM LANE, FULHAM, S.W.6

We don't need to tell YOU *the advantages of Refrigeration—*

A page your wife will like to look at

But do you know those of Frigidaire?

its silence—its *automatic* protection of food—its special compartment for fresh vegetables—its cold Control—its new and handy ice cube tray

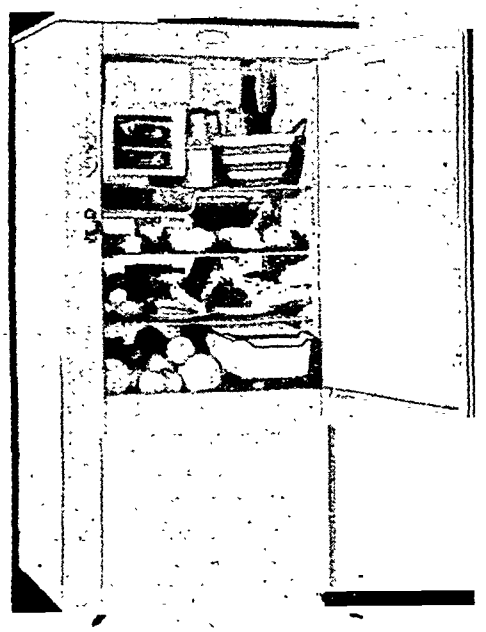
The Quickube Ice Tray, enabling single cubes, or many, or all, to be extracted at once, simply by a light pressure of the finger. No melting them out under the water tap. Your cocktail ice is ready at a moment's notice.

•

The Cold Control, by which the freezing of ice cubes or any other frozen delicacy can be accelerated at will.

•

The automatic feature of Frigidaire is invaluable. It cuts out the human element with its forgetfulness and consequent waste. Frigidaire maintains a dry cold that is *always* under 50°—the only safe temperature for food.



Practical flat top.

•

The Hydrator—a *moist* cold compartment, for fresh vegetables, sandwiches, etc., etc. Even wilted vegetables will regain their crispness here in a few hours.

•

Ease of installation. A Frigidaire only needs connection with your electric supply. No plumbing is necessary.

•

The new Frigidaire is quiet—you can't hear it start, stop or run.

UNQUESTIONABLY, Refrigeration is this decade's most important contribution to Health. Its benefits are enjoyable in the most practical, dependable and economic way through Frigidaire. And Frigidaire is now so easy to buy, on our special terms, that we urge you to get our quotation now by filling in the coupon below. There is, of course, no obligation whatsoever.

Showrooms at 141, New Bond Street, London, W.1, and in all principal towns.

COUPON

FRIGIDAIRE LIMITED (*Incorporated in Canada*)

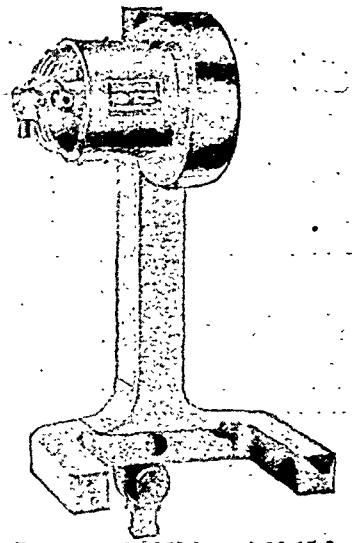
The "LIGHTNING" Machine for drying the Hands

The "LIGHTNING" Electric Machine dries the hands—by a 3-jet blast of warm air, quickly and hygienically—in 30 seconds. It provides the cleanest, safest, and most aseptic method, and the cost of *30 operations* is only *one penny*. The hands being thoroughly dried, all chapping or cracking is prevented. *Eliminates the use of towels and saves laundry charges.*

Invaluable in the Operating Theatre—for general Hospital use—and to Doctors and all those connected with the Medical Profession.

This new machine is a proved success and is making rapid headway. Send postcard for illustrated brochure.

Other "Icall" products include: "Everay" High-Frequency (Violet Ray) Apparatus; "Practicon" Machine for Massage, etc.; Radiant Heat Therapy Lamps; Ultra-Violet Lamps; Massage Vibrators, etc.



Price (Standard Voltages) £9 15 0
With foot switch £1 10 0 extra.

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of Potassii et Sodii Citro-Tartras and 30% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease, though eliminating deleterious nitrogenous products and favourably influencing circulation, glandular secretions, peristalsis, and metabolism.

The fruit acids of SALVITAE are converted *in the system into potentially basic alkaline* carbonates, thus enabling the blood to keep the uric acid compounds in solution, and *facilitate their removal.*

Write for samples and literature to

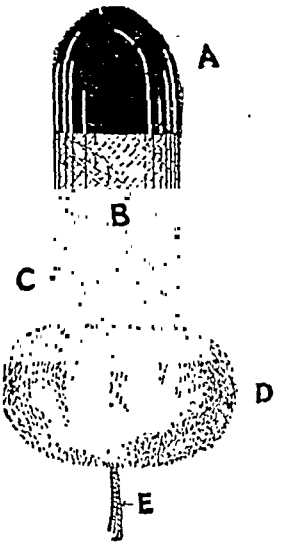
REGISTERED TRADE MARK

PONTAMPON

Patented in U.K. Regd. No. 113275.



A Perfect Method of Local Medication for Women.

Combining the medical qualities of a Vaginal Suppository with the mechanical support of a correctly shaped Tampon.

Pontampons consist of a semi-solid, slowly dissolving, medicated cone (A), supported by a compressed, *non-absorbable wool tampon* (B), encased in a thin gelatin shell (C). (D) protruding wool, (E) string for removal.

When introduced into the Vagina the gelatin shell slowly disintegrates; the compressed wool tampon expands, carrying the medicated cone upward against the cervix, where it slowly dissolves, thus affording a continuous application to the inflamed and congested mucous membrane of the entire vaginal tract.

As a means of applying local treatment in **Gonorrhoea Endometrits, Cervicitis, Vaginitis, Leucorrhoea, Dysmenorrhoea, Prolapsus Uteri, &c.,** Pontampons present the most Simple and Satisfactory method.

STOCK MEDICATIONS

(a) Ichthyolatum. (b) Ichthyol 10%. (c) Protargol and Ichthyol āā 2%. (c) Glycerol of Tannin 50%. (f) Ichthyol Compound ō Iodide of Silver. (g) Pure Glycerine.

Special formulae made up: such as Protargol, Argyrol, Ichthyol and Sulphur, Subacetate of Lead, Iodine in Glycerine 1%, &c., &c.

Pontampons are issued in three sizes, small, medium, and large.

SAMPLES will be sent to any physician who will make application to

THE PONTAMPON CO. (V. A. BLENKINSOP) **55, Holborn Viaduct, London, E.C.1.**

CEREBRO-SPINAL MENINGITIS

DURING epidemics, or seasonal rise of prevalence, many become CARRIERS of the MENINGOCOCCUS, the causative agent in the Nasopharynx. DISINFECTION is then the best method of protection from attack.

Of all disinfectants DIMOL SNUFF is the most convenient and efficient. CONVENIENT because it is supplied in powder form in neat pocket containers, available for use at any time, anywhere, without trouble. EFFICIENT because, even when diluted with **10 times its bulk** of mucus, Dimol Snuff KILLS IN 32 SECONDS the meningococcus, the cause of the condition.

By the nature of the snuff, by which it becomes sticky in the presence of moisture, it adheres to the mucus of the nasopharynx and becomes dissolved. Unlike liquids, the action is therefore long-continued.

DIMOL SNUFF

Prices and particlars will be sent on application to DIMOL LABORATORIES LTD., 40, LUDGATE HILL, LONDON, E.C.4

5% of pure iron (Fe) in readily assimilable form

. . . does not constipate, disturb digestion or discolour teeth

Colloidal Iron Concentrate	83%
Pure Alcohol	6%
Sugar	10%
Flavouring	1%

That is the formula of this tonic preparation, which contains a larger percentage of assimilable iron than has hitherto been provided in either a general or colloidal form. A more rapid response may therefore be anticipated from the administration of this preparation, which is very pleasant to take and well tolerated by all patients.

Idozan has no constipating effect, it does not derange the stomach or discolour the teeth. Though incompatible with alkaline salts, it may be combined with Liq. Arsenicalis and vegetable tinctures. It is therefore very suitable for therapeutic administration, where it is desired to give large doses of iron; both as a restorative after illness and in cases of anæmia it can be prescribed either with or without additional drugs with confidence and freedom.

IDOZAN

IDOZAN HAS BEEN REGULARLY PRESCRIBED BY DOCTORS IN FIFTEEN DIFFERENT COUNTRIES

PREFERRED BY THE MEDICAL PROFESSION FOR NEARLY A CENTURY

these essences rouse appetite and aid digestion

Just on a hundred years ago Brand & Company first introduced their Meat Essences. From that time until now Brand's Essences of Beef or Chicken have achieved fame because of the exclusive process and hygienic conditions under which they are manufactured.

Scientific tests have proved that these Essences are assimilated by the digestive organs 40 minutes quicker than ordinary foods and without the formation of residue.

99 out of every 100 doctors recently interviewed recommend Brand's Essences of Beef or Chicken in cases of intestinal disturbances, in fevers, before and after operations, and particularly in all cases where the patient's recovery is hampered by anorexia.

Brand's Essences are the pure juices of the finest freshly killed English meats, extracted by an exclusive process with no other substance added. Samples will be sent on receipt of a professional card. Dept. F.28, Brand & Co., Ltd., Mayfair Works, Vauxhall, London, S.W.8

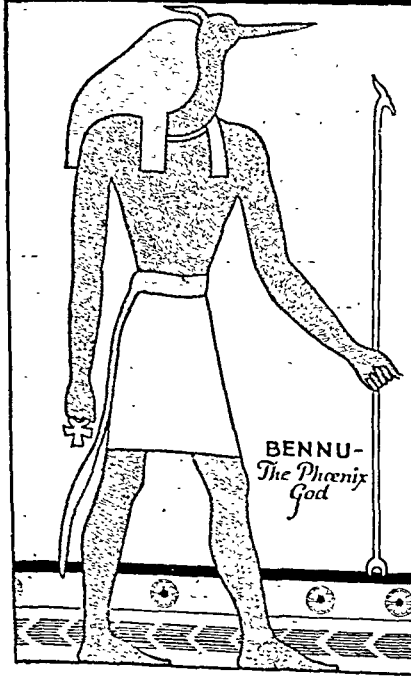
OVALTINE



IN NEURASTHENIA.

Every potential neurasthenic is greatly assisted by liberal drinking of "Ovaltine." It is recommended as a between meals beverage or as a mid-day "light lunch," and it displaces tea or coffee with complete advantage.

"Ovaltine" is also invaluable when taken at the hour of sleep. Its use in this way has often avoided the need for employing hypnotic drugs.

The value of "Ovaltine" has been proved many times in such cases. It provides nourishment of the right kind, and in a form readily dealt with by the impaired digestive organs. "Ovaltine" permits of the liberal ingestion of food without taxing the digestive power.

"Ovaltine" is a complete natural food, yielding in one cupful a greater food value than three eggs. This delicious beverage is unquestionably a tonic nerve nutrient of a high order.

A liberal supply for clinical trial sent free on request.

Reaching Laryngeal and Bronchial Inflammations

MANY laryngologists are advising the treatment of laryngeal, tracheal and bronchial inflammations by the direct route, nebulized spray solutions—in addition to the use of oral medication.

Mistol is ideally suited to this form of administration. When used in a nebulizer, it forms *an exceedingly fine, almost invisible, vapour. This spray is unirritating to the upper* respiratory passages and is drawn into the larynx and bronchi with each inspiration. In this way it reaches and exerts its therapeutic action upon the upper respiratory passages.

The ingredients of Mistol—menthol, camphor, eucalyptol, and chlorbutol in high-grade liquid paraffin—are endorsed by all leading rhino-laryngologists.

They relieve congestion and hyperemia in inflamed mucous membranes, diminish abnormal secretions, and aid in the return to normal conditions.

More and more physicians are finding in Mistol administered by means of a nebulizer a valuable ally to oral medication for laryngeal, tracheal, and bronchial inflammations.

Nutritional Necessities of Childhood

'. . . the fundamental problem is one of nutrition . . .' (*Lancet*, Jan. 5, 1929).

The article from which the above quotation is taken deals with the question of the health of children, the prevention of minor ailments and the treatment of serious disease; in it the necessity of the '*nutritional standpoint*' is emphasised.

The average diet of to-day does not furnish a sufficiency of Vitamins A, B and D.

Herein lies the value of Radio-Malt.

Radio-Malt supplies Vitamins A B_1 B_2 and D in standardised amounts and in the proportions harmonised to ensure the production of optimum effects. It builds up reserves of resistance against disease and is definitely anti-infective in action; also it promotes healthy growth and ensures correct calcium metabolism with resulting normal development of bones and teeth.

The pediatrician finds, therefore, in Radio-Malt the key to the problem of the nutritional necessities of childhood.

A NEW ISSUE

of the

Medisoaps Blotter

This has been prepared exclusively for the use of the medical profession. Got up in a dignified style, it contains much useful information dealing with Medisoap therapy, i.e., the treatment of skin diseases by means of Medisoaps. A therapeutic index adds to its convenience.

A copy will be sent with pleasure on application to Evans' Biological Institute, Higher Runcorn, Cheshire. The word MEDISOAP is a registered trade mark for the medicated soaps made by Charles Midgley, Ltd., Manchester. In a variety of formulae this method of skin medication has been brought into favour by the ease with which applications can be made and the certainty of absorption through regularity of use by the patient.

Associated with EVANS SONS LESCHER & WEBB, LTD., Liverpool & London.

'ZYMINE' Peptonising Tubes

(FAIRCHILD)

For the preparation of Peptonised Milk and other Predigested Food for the Sick.

'Zymine' Peptonising Tubes have been in use since 1882, making it possible for physicians to assure proper nutrition to their patients, even in cases where digestive power has been reduced to its lowest terms, and enabling chronic dyspeptics, invalids, convalescents, etc., who must live upon fluid foods for more or less prolonged periods, to take milk in quantities sufficient to maintain nutrition and promote restoration.

PEPTONISED MILK presents all the nourishment of plain milk freed from the objectionable qualities which constitute so serious a drawback to the utilisation of milk in the feeding of the sick. And of the many methods employed to make milk an available food for the sick, there is none that approaches the 'Fairchild' peptonising process in the certainty with which it accomplishes the desired purpose.

Supplied in boxes containing 6 and 12 Tubes.

The contents of one Tube will peptonise one pint of milk.

Nutrition and New Studies of Vitamins

More than ten years ago it was suggested that the yellow pigmentation (due to the presence of carotenoids) of certain foodstuffs was connected with the presence of Vitamin A in those foodstuffs.

As stated in the Report of the Medical Research Council, 1929-1930, more recent investigation has shown that Carotene can effectively replace Vitamin A in the diet; indeed, the work of one investigator seems to prove that Carotene is actually the precursor of this vitamin, inasmuch as when it is fed to animals it causes an accumulation of Vitamin A in the liver fat. Consequently, the administration of Carotene would appear to be for all practical purposes equivalent to the administration of Vitamin A.

The British Drug Houses have been producing Carotene in a pure crystalline state for some twelve months past, and it has been available for medical use since May, 1930.

Carotene B.D.H. is issued in sugar-coated pellets, each pellet containing 2 mg. of pure crystalline Carotene. Their administration may be regarded as giving an equivalent dose of Vitamin A.

CAROTENE B.D.H.

The pellets are issued in bottles of 50 and can be obtained through the principal pharmacists at 6/- per bottle—less the usual discount to medical men.

Local Anæsthesia in Surgical Practice

OPERATION ON BRAIN.

Typical Case.

A. B., aged 42 years.

Diagnosis: Advanced optic neuritis.

Anaesthesia: 60 c.c. of a 0.7 per cent. Novocain-Adrenaline solution.

Operation: A transverse infiltration block was made above the external ear with a vertical line along the proposed line of incision. The skull was opened over an area of 5 by 7 cm. The dura was opened after the ligation of two arterial branches. The opening was covered by the temporal muscle and the skin closed with silkworm gut.

Note.—The patient remarked at the finish of the operation that if this was all there is to such an operation he would not mind having one every day.

—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

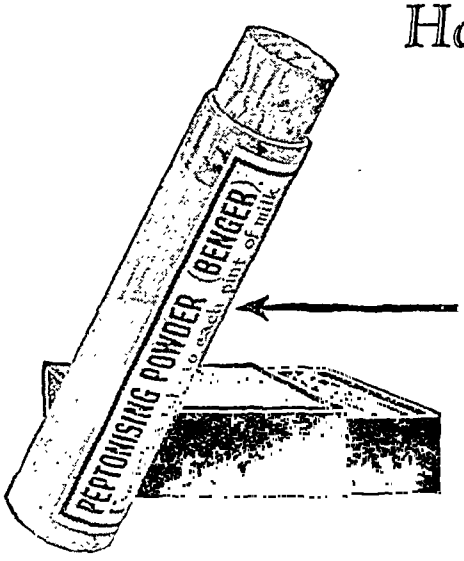
The most efficient Peptonising Powders!



Half a tube of Benger's is enough!

While half a tube of Benger's Peptonising Powders is enough to peptonise a pint of milk, gruel or soup, in most cases in 10 minutes, the extent of the peptonising action can be regulated by either increasing or diminishing the quantity of the powders, and by lengthening or shortening the time during which they are allowed to act on the milk, gruel, etc.

Generally speaking, Benger's Peptonising Powders produce the required result with half the quantity necessary of other preparations, whose initial cost also is higher.

Prices:
No. 1—Box of 6, 1/-; No. 2—Box of 12, 1/8

Benger's Liquor Pancreaticus.

An important aid in the preparation of Peptonised Milk, etc.

Benger's Liquor Pancreaticus is an active solution of the digestive principles of the Pancreas; a really efficient agent for the digestion of milk, gruel, and farinaceous or partly farinaceous foods. Benger's Liquor Pancreaticus is odourless and tasteless.

In 4, 8 and 16-oz. bottles.

Prices: 3/-, 5/6 and 10/6

BETTER MILK FOR BABIES

Introducing LACTOGEN

to the British Medical Profession

Lactogen—prepared in England by Nestlé's—is a modified dried milk for use in infant feeding. On reconstitution it closely approaches the maternal standard.

This *correct balance* is secured by a scientific adjustment of the constituents, whilst the full *vitamin content* of the raw milk is carefully conserved.

Lactogen is easily *digested* by reason of the modified character of the fat and protein.

The *hygienic packing* precludes contamination, and the aluminium measure packed in each tin ensures *accurate feeds.*

Lactogen is neither a new nor untried product. First introduced in Australia, it has for many years enjoyed a large sale in overseas countries.

FREE SAMPLES with detailed descriptive literature will be sent to any Member of the Medical Profession upon request.

"VIODAR"

(R.T.M. applied for)

VIODAR is the new standardised stable antiseptic containing FREE IODINE IN OILY CONDITION, to which its violet colour is due. Viodar is issued in two strengths, namely, 1 in 1,000 and 1 in 200.

VIODAR can be used both Locally and nternally. For many purposes it should replace Tincture of Iodine.

VIODAR is neutral and will not develop acidity on storage. Although stable in stoppered bottles, Iodine is liberated from Viodar on contact with the warmth of the part to which it is applied.

VIODAR does not stain or sting. The 1 in 1,000 strength is tasteless. The oily form of solution enhances the penetrating power, and at the same time the preparation is occlusive and protective. Viodar 1 in 1,000 should prove effective for general purposes—the 1 in 200 may prove too strong on mucous membrane.

VIODAR should be tried in skin affections.

Internally, VIODAR 1 in 1,000 is suggested as a lubricant stomach and intestinal antiseptic. The antiseptic power of Viodar has been demonstrated clinically.

VIODAR 1 in 200 permits of bold dosage—for Free Iodine effect in less vehicle.

In general the preparations have the well-known medicinal properties of the Iodides.

Bottles 3/- & 5/-.

(Aesculapius)

THE ANAEMIAS

PERNICIOUS ANAEMIA.

Careful observations of large numbers of cases and the numerous notable reports received during the last four years justify the assertion that if treatment with HEPATEX is properly carried out, marked benefit results in most cases within a few days. Should the improvement not occur within three weeks it is probable that it is not a case of Pernicious Anaemia, or there may be some factor intimately connected with the gastric aspects of the condition which does not respond to Liver Therapy. For such cases attention has recently been turned to the haematopoietic value of stomach tissue with promising results, and in this connection we have produced GASTREXO, a scientifically prepared desiccated and defatted whole stomach substance.

SECONDARY ANAEMIA.

For the treatment of the Severe Secondary Anaemias the use of Hepatex in itself may be of inconstant value, but combined with iron it has proved to be eminently satisfactory. For cases of stubborn Secondary Anaemia, where powerful stimulation of the blood regenerating organs is highly desirable, HEPATEX WITH IRON is strongly recommended. The special form of iron used is greatly superior to ordinary iron preparations as regards assimilation and produces no disagreeable after-effects.

HEPATEX	HEPATEX with IRON.	GASTREXO
issued in 4 oz. bottles. One fluid drachm equals 2 oz. of fresh liver.	issued in 2 oz. bottles. Contains one grain of metallic iron in one drachm.	issued in boxes of 12 × 10 grammes and tins of 240 grammes. 10 grammes is equivalent to 80 grammes of whole substance.

ROMAN RELIEF DEPICTING A GERMANIC LADY AS SHE TRAVELLED DURING THE TEUTONIC MIGRATIONS.—Greek and Roman records, together with archæological finds, show us the Teutonic barbarian tribes in their earliest habitat—in Southern Sweden, Jutland, Schleswig-Holstein, on the coast of what is now Germany eastward as to the Oder, and in the islands as far as Gothland. They seem to have been driven thence by encroachments of the sea and by inundations. This earliest movement led to widespread migrations into the whole of central southern and western Europe, especially from the last quarter of the fourth century to the end of the eighth—with momentous results for modern Europe. The Teutonic movement was not a matter merely of armies setting forth to conquer, but of the migration and re-settling of whole populations, the women and children, goods and chattels being transported in wagons. The illustration here reproduced from a relief upon the column of Marcus Aurelius shows us a Teutonic lady and child of the second century A.D. travelling in an ox-waggon.

DATE:—A.D. c. 370—c. 500 (Pioneering period of the migrations).

THE TREATMENT OF MITRAL DISEASE IN CHILDREN*

BY

THOMAS F. COTTON, M.D., C.M., M.R.C.P.

PHYSICIAN TO OUT-PATIENTS, THE NATIONAL HOSPITAL FOR DISEASES OF THE HEART

Mitral disease in children is a serious malady, and ranks in this country among the most important of killing diseases in childhood and adolescence. It is a disease of the school child, and is a principal cause of permanent invalidism among children of the poorer classes attending elementary schools. The State recognizes in juvenile rheumatism, the cause of the disease, a cardiac problem closely related to the environmental conditions associated with their growth and education. It has provided schools for physically defective children, which are available for the child with rheumatic heart disease. At these schools, with good medical supervision, the hours of study, transport, and other conditions of school life are regulated with a view to improving or maintaining their health and providing an education that will help them to earn a living.

Special convalescent homes have also been established for children in the London area with rheumatic heart disease requiring treatment before resuming their school life. The Metropolitan Asylums Board have recently transferred to the London County Council for this purpose one hundred beds at Queen Mary's Hospital, Carshalton, and at Highwood Hospital, Brentwood, and proposals have been accepted for increasing the number. Convalescent homes have been provided, and are controlled and managed by a charity organization working in association with the Board of Education. The Invalid Children's Aid Association, a pioneer in this form of institutional treatment, has two special convalescent homes for children with rheumatic heart affections: one with seventy-five beds for girls at West Wickham, Kent, and the other at Willesden, with twenty-two beds for boys. The Edgar Lee Home at Willesden was founded in 1919, and in June, 1930, 678 boys had been admitted for treatment. There is a matron in charge, assisted by a nurse, and a schoolmistress is provided by the Board of Education. A general practitioner, living in the neighbourhood, makes visits weekly, or oftener if necessary, and there are two consulting physicians. It has been my practice since 1919 to examine all the boys once a month, and make notes on their condition.

General Description of Selected Cases

It seems desirable, now that ten years have elapsed since the home was opened, to review the results of the treatment that has been carried on at this institution. For this purpose I have selected the first 100 boys admitted in the years 1919–22 with rheumatic heart disease, and have obtained the after-histories of all but six of these, after seven years in one group and eight years in the other. Their ages on admission were between 10 and 11 years. All had had rheumatism or chorea, and many were convalescent from a recent rheumatic infection. They were admitted from the general hospitals of the metropolitan area, or from the schools on the recommendation of the school medical officer. All but two of these boys had signs of a rheumatic infection of the heart.

57 were diagnosed as having mitral disease.
23 had signs of mitral stenosis.
14 had signs of mitral stenosis and aortic regurgitation.
4 had aortic regurgitation alone.
2 had no signs of valve disease.

* A British Medical Association Lecture delivered to the Cardiff Division on January 14th.

Mitral disease in children is probably always associated with a rheumatic invasion of the myocardium, and is evidence of carditis. The symptoms in the early years are those of a general infection. At a later period in the advanced stages of the disease they fuse with, or are replaced by, symptoms of a failing myocardium. These children were not advanced cases of myocardial disease, and did not have, on admission to the home, signs of congestive heart failure. The heart, with a few exceptions, was enlarged in the mitral stenosis group; in the mitral systolic group there were no signs of cardiac enlargement in the majority of cases. They had symptoms and signs of a general infection, and our chief concern was to determine whether the infection was active or quiescent, for it was upon this decision that we based the treatment.

Signs of Active Rheumatic Infection

Pyrexia, pallor, loss of weight, nodules, and a rapid pulse rate were regarded as signs of an active infection. The length of treatment in the home averaged four and a half months; 20 per cent. were in a stage of active infection, and during a part of this time were kept in bed on this account. A temperature ranging from 99° to 99.6°, if not accompanied by loss of weight or a rapid pulse rate, did not seem to be affected by rest, and, as a doubtful sign of infection, was disregarded. Pyrexia of more than 99.6° was an indication for rest in bed for several weeks or months, so long as it continued, and was usually accompanied by pallor, loss of weight, tachycardia, and in some cases rheumatic nodules. Nodules might occur without any rise of temperature, and were an indication for complete rest until they had disappeared. A small percentage of patients were kept in bed on account of a tachycardia with a resting pulse rate of 100 or more, as an isolated sign of infection. A rapid heart rate present during the waking hours but absent with the child asleep, without a rise of temperature or loss of weight, was considered a doubtful sign of infection and not an indication for complete rest. Pallor, when conspicuous, was usually associated with some other sign of infection. Arthritis, joint pains, and other articular signs in a large number of cases played a minor part in the diagnosis of a recurring rheumatic infection.

Treatment

If there were no signs of active infection, and no complaint of breathlessness, undue exhaustion, or fatigue at rest, or after running about the house or grounds, such games as football and cricket were allowed, or less strenuous games if the exercise tolerance was poor. The matron's report on the boys' reaction to exercise helped, in deciding what games should be played. The games, study hours, and resting periods were regulated by the presence or absence of signs of infection, symptoms of fatigue and exhaustion, and response to effort, rather than by any variation in the heart signs. A striking feature in the examination of the heart was the constancy of the physical signs. It was found that frequent examinations of the heart were unnecessary in recognizing changes in the condition of the patient.

Salicylates were given a good trial, and were not found helpful in controlling the pulse rate or the pyrexial curve, except in those with a high temperature in the course of an acute rheumatic infection. Digitalis, when given in moderately large doses, did not slow the pulse rate in those with a persistent tachycardia. General tonics were sometimes prescribed. Good healthy food, with plenty of butter and milk, was found to be more important than drugs in the treatment of this disease. It has been our practice to enucleate the tonsils, if they were septic, at the local hospital during the course of treatment.

Results obtained from Investigation of After-Histories

In all but 6 of the 100 cases a diagnosis was made of mitral disease or mitral stenosis. In 57, the larger group, mitral disease with a mitral systolic murmur was diagnosed. As shown in the table, 17, or 29 per cent.,

	Total	Dead	Living	Duration	Untraced	Remarks
Mitral disease, mitral systolic murmur	57	17 (29%)	35 (61%)	7 yrs.	3	2 living after 6 years
Mitral stenosis	23	15 (65%)	6 (25%)	8 yrs.		1 living after 7 years 1 living after 4 years
Aortic regurgitation and mitral stenosis	14	6 (43%)	6 (43%)	8 yrs.	2	
Aortic regurgitation, no valve disease, congenital	6					
	100	38	47		5	

were dead, and 35, or 61 per cent., were alive at the end of seven years, 2 were alive after six years, and 3 could not be traced. In a smaller group of 23 there were definite signs of mitral stenosis ; 15 of these, or 65 per cent., were dead, and 6, or 26 per cent., were living after eight years, 1 was alive at the end of seven years, and another after four years. In the smallest group there were 14 with mitral stenosis and aortic regurgitation ; 6 of these were dead and 6 living, or 43 per cent., after eight years ; 2 could not be traced. No after-histories were obtained in the remaining 6 cases.

Mortality from Mitral Disease and Mitral Stenosis

The mortality rate, as one would expect it to be, is considerably higher in the mitral stenosis group, with 65 per cent. in one, and 43 per cent. in the other, or 57 per cent. if the two groups are combined, than in the mitral disease group with a mitral systolic murmur, and a death rate of 29 per cent. It is well known that a mitral systolic murmur is an unreliable sign of mitral disease. It is a more certain sign in children who have had rheumatism, as was the case in these patients. In this mitral systolic group the murmur may have been functional in some ; the mitral valve may not have been damaged, and the heart not affected by the rheumatic infection. In a few, because of the loudness of the murmur, the short diastolic murmur of early mitral stenosis may have been missed. I do not think these problematic diagnostic errors materially alter the significance of these figures in this group of 57 cases.

There were undoubted signs of mitral stenosis in the remaining 37 cases. There is the possibility of an error in the diagnosis of aortic regurgitation in patients with mitral stenosis. In the 14 cases diagnosed aortic regurgitation and mitral stenosis, the death rate was lower than in the group of 23 with mitral stenosis alone. We might have expected a larger number of deaths in these cases, but the total is too small to stress this point.

Conclusions

In comparing the figures of the two main groups—57 with a mitral systolic murmur, and 37 with mitral stenosis —it has to be noted that the after-histories are for seven years in one and eight years in the other. It is probable that the death rate would have been higher than 29 per cent. at the end of eight years in the mitral systolic group, and lower than 65 per cent. at the end of seven years in the mitral stenosis group. Nevertheless, these figures have an absolute and relative value that the variable factors which have been considered cannot alter. They allow the statement to be made that the prognosis in children with mitral stenosis over a period of eight years who have had treatment in a special convalescent home is a grave one. They raise the question of the value of this form of treatment in mitral stenosis, and whether it is worth while treating such cases in a special convalescent home.

The figures in the mitral systolic group confirm what is well known, that the prognosis is much more favourable in mitral disease in children before the signs of mitral stenosis have developed. They suggest that in early cases treatment in a special convalescent home may play a not unimportant part in controlling the course of the disease.

It has to be admitted that the treatment of a chronic disease like rheumatism, with the cause unknown, is unsatisfactory. This is particularly true in the treatment of children who belong to the poorer classes. On leaving the convalescent home, where they have been more or less protected against reinfection, they return to unhealthy homes, and are again exposed to rheumatic and other infections which cause more damage to the heart muscle and valves. The children of well-to-do parents are better protected against the ravages of rheumatism, for they have home surroundings in which they can live, grow up, and be educated under conditions which are comparable with those which exist in a special convalescent home. The prognosis is more favourable in these children, because the disease is likely to be recognized in its early stages, and suitable treatment given at a time when it is possible to prevent the development of progressive changes leading to a serious cardiac disability.

The mortality rate in mitral disease occurring in children from the elementary schools, I am convinced, can be lowered if they are given treatment in a special convalescent home before signs of mitral stenosis have developed. This treatment should be continued over a longer period than has been possible hitherto from lack of bed accommodation. If treatment were limited to those patients with early signs of disease, more beds would be available and courses could be prolonged.

THE PROSTATE IN GENERAL PRACTICE*

BY

KENNETH WALKER, F.R.C.S.

SURGEON IN CHARGE, GENITO-URINARY DEPARTMENT, ROYAL NORTHERN HOSPITAL ; SURGEON TO ST. PAUL'S HOSPITAL ; SURGEON IN CHARGE, VENEREAL DISEASES DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL

The prostate is an organ which is of far greater importance to the clinician than to the anatomist or the physiologist. To the anatomist it is merely a glandular structure, fitting round the neck of the bladder, and no bigger than a chestnut ; to the physiologist it is an accessory sex gland whose function is so unimportant and so obscure that it has not yet been discovered. To the clinician, however, the prostate is particularly liable to disease, which may occasion disturbances of general health utterly out of proportion to the part the organ plays in the economy of the body. This difference between the roles of the prostate in disease and in health is entirely due to its position at the " cross-roads " of the urinary and genital systems, which are almost bound to suffer when the gland is diseased. For this reason it may be of interest to survey, from the standpoint of the general practitioner, some of the disturbances in general health that may result from a lesion of the prostate.

* Based on a paper read before the St. Pancras Division of the British Medical Association.

TYPES OF DISEASE

It will be convenient for the purpose of this paper to consider prostatic diseases under five headings: (1) inflammatory lesions of the prostate; (2) prostatic enlargement; (3) malignant disease; (4) neuroses; (5) other conditions.

Inflammatory Lesions

A prostatitis may be acute or chronic. If it is acute the symptoms are usually so striking that no doubt is left as to the nature of the disease. Chronic prostatitis, however, may present itself to the practitioner in many guises, and consequently errors in diagnosis are common, even when the patient complains of symptoms (since they are both urinary and genital in character) that should point clearly to the fact that the disease is located at the cross-roads. Most commonly there is frequency and pain on micturition, and deep-seated discomfort in the perineum after sexual excitement. Some patients will come on account of pain felt elsewhere in the genital tract—at the end of the penis, over the sacrum, in the groin, or in either testicle. They may also state that recently, and as far as they can see without reason, their testicles have become swollen. They may even recall that they were plagued with a similar visitation some months or years previously. Possibly they may have noted from time to time a tiny drop of urethral discharge at the meatus, or some inexplicable threads in the urine. Often these helpful observations are lacking.

There are certain points worthy of attention in connexion with chronic inflammation of the prostate. The first is that frequency and pain, a combination we are generally taught to associate with a lesion of the bladder, are just as likely to be the result of a lesion of the prostate. The second is that an absence of history of gonorrhoea does not exclude the possibility of a prostatitis. We are apt to assume that the genital tract is the privileged hunting ground of the gonococcus, and that other organisms find difficulty in establishing a footing in these regions. This is an absurd assumption. The prostate is a favourable field of action for any lucky microbial invader, and once organisms entrench themselves in the labyrinthine passages of the gland they are dislodged only with the greatest difficulty. If a patient complains of symptoms that may be due to a chronic infection of his prostate we must not be put off because he is above gonococcal suspicion. A rectal examination should be insisted upon; the prostate and vesicles should be carefully palpated, and if possible some secretion expressed for microscopical investigation. A chronic focus in the prostate may also give rise to signs and symptoms that seem entirely remote from any lesion of the genital tract. The patient may complain merely of vague pains over the lumbo-sacral region, or he may appear in the consulting room as a case of "sciatica" or of "chronic rheumatism." Sometimes the case is still more carefully disguised as one of *recurrent iritis*. Next to the teeth, the prostate is most commonly the primary focus of infection in cases of chronic fibrositis or synovitis. Droitwich and Harrogate, and other famous watering-places at which rheumatic patients congregate, are full of cases of undetected prostatitis.

Prostatic Enlargement

I need not enlarge upon the obvious cases of prostatic enlargement. An elderly man who complains of increasing difficulty of micturition and of nights disturbed by the necessity of rising is not likely to leave the consulting room without a diagnosis of his case. But sometimes a patient whose troubles are the result of prostatic obstruction consults his doctor about the subject of his general health rather than of micturition troubles. Indeed, I have known a patient whose bladder was half-way to his umbilicus announce on arrival that he had come on account of nausea and vomiting. Only after examination and careful interrogation did it transpire that the gastric symptoms were preceded by a long history of micturition trouble, and that the vomiting was actually symptomatic of commencing uraemia. Such cases are by no means rare. To many men, a certain amount of frequency and difficulty is inevitable in old age. "My bladder has been weak for some years, but of course one has to put up with that sort of inconvenience when one gets on in years," is a familiar statement reflecting a common attitude of mind. Consequently, but little is said of the weakness, and attention is concentrated on other and more serious inconveniences. Even the doctor may be hoodwinked at times, and may be content with a general overhaul of the patient, followed by an examination of the urine and the finding of albuminuria. The dry mouth, anorexia, thirst, headache, nausea, and vomiting, taken in conjunction with the raised blood pressure and albuminuria, all fit in with a diagnosis of chronic nephritis, and the patient may leave the consulting room without the discovery being made that the renal trouble is secondary to a long-standing prostatic obstruction.

In other cases I have known the gastro-intestinal symptoms not uncommonly associated with prostatic enlargement to divert attention to the alimentary canal. A close connexion exists between the reflexes of micturition and defaecation, so that a man with a distended bladder may find it difficult or impossible to empty his rectum naturally; conversely, one with a loaded rectum may have similar trouble with his bladder. When the amount of residual urine in the bladder begins to increase, the action of the bowel is generally hampered, so that the patient, in addition to his urinary difficulty, complains of constipation, abdominal pain, and flatulence. To the Anglo-Saxon an interference with the daily evacuation of the bowels is of far greater moment than a weakness of his bladder, and it is this new development which often induces him to seek medical advice. Unless, therefore, the practitioner is thorough in his examination, his attention may be concentrated on the alimentary disturbances that are only of secondary importance, and miss the primary focus.

Malignant Disease of the Prostate

Carcinoma of the prostate is another example of a "silent" lesion. Not infrequently the chief disturbance of health to which it gives rise is general rather than local, so that the physician's attention is mainly directed to the debility and loss of weight. In other cases, the patient with a malignant prostate may appear in the consulting room complaining of intractable sciatica, or of constant pain in the lumbo-sacral region. The urinary symptoms may be comparatively slight, and the patient may not think it necessary to inform his doctor that his urinary stream has been getting progressively worse. One of the surprising features of the disease may be the smallness of the primary malignant focus as compared with the extensive secondary infiltrations of the sacrum and ilium. Palpation may discover only a slight hardening of one of the lobes, and yet a skiagram may reveal the fact that the pelvis is entirely eroded with growth. Recently I examined under an anaesthetic a patient who had consulted many doctors for pain in the lumbo-sacral region, with increasing debility. Had it not been for the favourable influence of the anaesthetic in facilitating the palpation of the prostate I doubt whether I should have detected a small hard nodule in one of the lobes. Yet a skiagram showed that his pelvis was the site of advanced secondary deposits. The *x*-ray appearances of the bones in these cases are very striking, and cannot be confused

Results obtained from Investigation of After-Histories

In all but 6 of the 100 cases a diagnosis was made of mitral disease or mitral stenosis. In 57, the larger group, mitral disease with a mitral systolic murmur was diagnosed. As shown in the table, 17, or 29 per cent., were dead, and 35, or 61 per cent., were alive at the end of seven years, 2 were alive after six years, and 3 could not be traced. In a smaller group of 23 there were definite signs of mitral stenosis; 15 of these, or 65 per cent., were dead, and 6, or 26 per cent., were living after eight years, 1 was alive at the end of seven years, and another after four years. In the smallest group there were 14 with mitral stenosis and aortic regurgitation; 6 of these were dead and 6 living, or 43 per cent., after eight years; 2 could not be traced. No after-histories were obtained in the remaining 6 cases.

	Total	Dead	Living	Duration	Untraced	Remarks
Mitral disease, mitral systolic murmur	57	17 (29%)	35 (61%)	7 yrs.	3	2 living after 6 years
Mitral stenosis	23	15 (65%)	6 (25%)	8 yrs.		1 living after 7 years
Aortic regurgitation and mitral stenosis	14	6 (43%)	6 (43%)	8 yrs.	2	1 living after 4 years
Aortic regurgitation, no valve disease, congenital	6					
	100	38	47		5	

Mortality from Mitral Disease and Mitral Stenosis

The mortality rate, as one would expect it to be, is considerably higher in the mitral stenosis group, with 65 per cent. in one, and 43 per cent. in the other, or 57 per cent. if the two groups are combined, than in the mitral disease group with a mitral systolic murmur, and a death rate of 29 per cent. It is well known that a mitral systolic murmur is an unreliable sign of mitral disease. It is a more certain sign in children who have had rheumatism, as was the case in these patients. In this mitral systolic group the murmur may have been functional in some; the mitral valve may not have been damaged, and the heart not affected by the rheumatic infection. In a few, because of the loudness of the murmur, the short diastolic murmur of early mitral stenosis may have been missed. I do not think these problematic diagnostic errors materially alter the significance of these figures in this group of 57 cases.

There were undoubted signs of mitral stenosis in the remaining 37 cases. There is the possibility of an error in the diagnosis of aortic regurgitation in patients with mitral stenosis. In the 14 cases diagnosed aortic regurgitation and mitral stenosis, the death rate was lower than in the group of 23 with mitral stenosis alone. We might have expected a larger number of deaths in these cases, but the total is too small to stress this point.

Conclusions

In comparing the figures of the two main groups—57 with a mitral systolic murmur, and 37 with mitral stenosis—it has to be noted that the after-histories are for seven years in one and eight years in the other. It is probable that the death rate would have been higher than 29 per cent. at the end of eight years in the mitral systolic group, and lower than 65 per cent. at the end of seven years in the mitral stenosis group. Nevertheless, these figures have an absolute and relative value that the variable factors which have been considered cannot alter. They allow the statement to be made that the prognosis in children with mitral stenosis over a period of eight years who have had treatment in a special convalescent home is a grave one. They raise the question of the value of this form of treatment in mitral stenosis, and whether it is worth while treating such cases in a special convalescent home.

The figures in the mitral systolic group confirm what is well known, that the prognosis is much more favourable in mitral disease in children before the signs of mitral stenosis have developed. They suggest that in early cases treatment in a special convalescent home may play a not unimportant part in controlling the course of the disease.

It has to be admitted that the treatment of a chronic disease like rheumatism, with the cause unknown, is unsatisfactory. This is particularly true in the treatment of children who belong to the poorer classes. On leaving the convalescent home, where they have been more or less protected against reinfection, they return to unhealthy homes, and are again exposed to rheumatic and other infections which cause more damage to the heart muscle and valves. The children of well-to-do parents are better protected against the ravages of rheumatism, for they have home surroundings in which they can live, grow up, and be educated under conditions which are comparable with those which exist in a special convalescent home.

The prognosis is more favourable in these children, because the disease is likely to be recognized in its early stages and suitable treatment given at a time when it is possible to prevent the development of progressive changes leading to a serious cardiac disability.

The mortality rate in mitral disease occurring in children from the elementary schools, I am convinced, can be lowered if they are given treatment in a special convalescent home before signs of mitral stenosis have developed. This treatment should be continued over a longer period than has been possible hitherto from lack of bed accommodation. If treatment were limited to those patients with early signs of disease, more beds would be available and courses could be prolonged.

THE PROSTATE IN GENERAL PRACTICE

This difference between the roles of the prostate in disease and in health is entirely due to its position at the "cross-roads" of the urinary and genital systems, which are almost bound to suffer when the gland is diseased. For this reason it may be of interest to survey, from the standpoint of the general practitioner, some of the disturbances in general health that may result from a lesion of the prostate.

* Based on a paper read before the St. Pancras Division of the British Medical Association.

TYPES OF DISEASE

It will be convenient for the purpose of this paper to consider prostatic diseases under five headings: (1) inflammatory lesions of the prostate; (2) prostatic enlargement; (3) malignant disease; (4) neuroses; (5) other conditions.

Inflammatory Lesions

A prostatitis may be acute or chronic. If it is acute the symptoms are usually so striking that no doubt is left as to the nature of the disease. Chronic prostatitis, however, may present itself to the practitioner in many guises, and consequently errors in diagnosis are common, even when the patient complains of symptoms (since they are both urinary and genital in character) that should point clearly to the fact that the disease is located at the cross-roads. Most commonly there is frequency and pain on micturition, and deep-seated discomfort in the perineum after sexual excitement. Some patients will come on account of pain felt elsewhere in the genital tract—at the end of the penis, over the sacrum, in the groin, or in either testicle. They may also state that recently, and as far as they can see without reason, their testicles have become swollen. They may even recall that they were plagued with a similar visitation some months or years previously. Possibly they may have noted from time to time a tiny drop of urethral discharge at the meatus, or some inexplicable threads in the urine. Often these helpful observations are lacking.

There are certain points worthy of attention in connexion with chronic inflammation of the prostate. The first is that frequency and pain, a combination we are generally taught to associate with a lesion of the bladder, are just as likely to be the result of a lesion of the prostate. The second is that an absence of history of gonorrhoea does not exclude the possibility of a prostatitis. We are apt to assume that the genital tract is the privileged hunting ground of the gonococcus, and that other organisms find difficulty in establishing a footing in these regions. This is an absurd assumption. The prostate is a favourable field of action for any lucky microbial invader, and once organisms entrench themselves in the labyrinthine passages of the gland they are dislodged only with the greatest difficulty. If a patient complains of symptoms that may be due to a chronic infection of his prostate we must not be put off because he is above gonococcal suspicion. A rectal examination should be insisted upon; the prostate and vesicles should be carefully palpated, and if possible some secretion expressed for microscopical investigation. A chronic focus in the prostate may also give rise to signs and symptoms that seem entirely remote from any lesion of the genital tract. The patient may complain merely of vague pains over the lumbo-sacral region, or he may appear in the consulting room as a case of "sciatica" or of "chronic rheumatism." Sometimes the case is still more carefully disguised as one of recurrent iritis. Next to the teeth, the prostate is most commonly the primary focus of infection in cases of chronic fibrositis or synovitis. Droitwich and Harrogate, and other famous watering-places at which rheumatic patients congregate, are full of cases of undetected prostatitis.

Prostatic Enlargement

I need not enlarge upon the obvious cases of prostatic enlargement. An elderly man who complains of increasing difficulty of micturition and of nights disturbed by the necessity of rising is not likely to leave the consulting room without a diagnosis of his case. But sometimes a patient whose troubles are the result of prostatic obstruction consults his doctor about the subject of his general health rather than of micturition troubles. Indeed, I have known a patient whose bladder was half-way to his umbilicus announce on arrival that he had come on account of nausea and vomiting. Only after examination and careful interrogation did it transpire that the gastric symptoms were preceded by a long history of micturition trouble, and that the vomiting was actually symptomatic of commencing uraemia. Such cases are by no means rare. To many men, a certain amount of frequency and difficulty is inevitable in old age. "My bladder has been weak for some years, but of course one has to put up with that sort of inconvenience when one gets on in years," is a familiar statement reflecting a common attitude of mind. Consequently, but little is said of the weakness, and attention is concentrated on other and more serious inconveniences. Even the doctor may be hoodwinked at times, and may be content with a general overhaul of the patient, followed by an examination of the urine and the finding of albuminuria. The dry mouth, anorexia, thirst, headache, nausea, and vomiting, taken in conjunction with the raised blood pressure and albuminuria, all fit in with a diagnosis of chronic nephritis, and the patient may leave the consulting room without the discovery being made that the renal trouble is secondary to a long-standing prostatic obstruction.

In other cases I have known the gastro-intestinal symptoms not uncommonly associated with prostatic enlargement to divert attention to the alimentary canal. A close connexion exists between the reflexes of micturition and defaecation, so that a man with a distended bladder may find it difficult or impossible to empty his rectum naturally; conversely, one with a loaded rectum may have similar trouble with his bladder. When the amount of residual urine in the bladder begins to increase, the action of the bowel is generally hampered, so that the patient, in addition to his urinary difficulty, complains of constipation, abdominal pain, and flatulence. To the Anglo-Saxon an interference with the daily evacuation of the bowels is of far greater moment than a weakness of his bladder, and it is this new development which often induces him to seek medical advice. Unless, therefore, the practitioner is thorough in his examination, his attention may be concentrated on the alimentary disturbances that are only of secondary importance, and miss the primary focus.

Malignant Disease of the Prostate

Carcinoma of the prostate is another example of a "silent" lesion. Not infrequently the chief disturbance of health to which it gives rise is general rather than local, so that the physician's attention is mainly directed to the debility and loss of weight. In other cases, the patient with a malignant prostate may appear in the consulting room complaining of intractable sciatica, or of constant pain in the lumbo-sacral region. The urinary symptoms may be comparatively slight, and the patient may not think it necessary to inform his doctor that his urinary stream has been getting progressively worse. One of the surprising features of the disease may be the smallness of the primary malignant focus as compared with the extensive secondary infiltrations of the sacrum and ilium. Palpation may discover only a slight hardening of one of the lobes, and yet a skiagram may reveal the fact that the pelvis is entirely eroded with growth. Recently I examined under an anaesthetic a patient who had consulted many doctors for pain in the lumbo-sacral region, with increasing debility. Had it not been for the favourable influence of the anaesthetic in facilitating the palpation of the prostate I doubt whether I should have detected a small hard nodule in one of the lobes. Yet a skiagram showed that his pelvis was the site of advanced secondary deposits. The *x*-ray appearances of the bones in these cases are very striking, and cannot be confused

with those of any other condition except Paget's disease. I would strongly advise any practitioner who suspects that his patient has a malignant prostate to lose no time in obtaining an *x*-ray of the pelvis. I can recall other cases in which even a careful rectal examination gave doubtful results, and yet the whole of the pelvic girdle was infiltrated with disease. Indeed, it may be said that whenever secondary bony deposits are discovered in an elderly man who has no obvious primary lesion, the prostate should be carefully investigated.

The Prostate as a Starting Point of a Sex Neurosis

Under this heading are included many cases of a rather obscure nature. There is no organ in the male body more frequently used as the peg on which to hang a neurosis than the prostate gland. This is undoubtedly due to the fact that the prostate has a large nerve supply, and that as an organ of sex its activity is linked up with the emotions. We have all been consulted by patients who complain of deep-seated pain in the neighbourhood of the prostate for which no cause can be discovered. Some of these patients have previously suffered from chronic gonorrhoea with prostatitis. Although by dint of conscientious treatment the prostatic focus may have cleared up, the pain is apt to remain. An additional symptom sometimes complained of is frequency of micturition, which is not continuous, but comes on in attacks which are likely to be associated with an increase of pain in the perineum, or at the end of the penis. Not uncommonly the sex act is rendered difficult for these patients by the existence of premature ejaculations or post-coital discomfort. The anxiety associated with the condition and the fear that it will lead to impotence is very likely to result in a general neurasthenia. I recollect the case of one patient who had prostatic massage for two years, and finally became so desperate that he attempted to commit suicide. On examining his prostate I could find nothing wrong with it, and a microscopical investigation of the expressed secretion showed a complete absence of pus cells. He was cured by reassurance, complete cessation of all treatment, and a holiday in Switzerland. It is possible that in some cases the symptoms are caused by a condition of congestion of the prostate, and in others to spasm of its muscle fibres. If a routine examination is made of prostates in the post-mortem room, it will be found that thrombosis in the prostatic plexus is of very frequent occurrence, and I am convinced that the pain complained of by some patients in whom no obvious disease exists, is due to circulatory disturbance associated occasionally with this vascular condition. For this type of case I have found gentle prostatic massage and diathermy applied through a rectal electrode of greatest use. Many cases have yielded to this treatment, especially when it is accompanied by assurance, suggestion, and attention to the general physical and mental health. Electricity is associated in all patients' minds with the idea of magic, and, used properly, it often has a magical effect.

Other Conditions

There are many other conditions of the prostate that might be included in this survey of prostatic lesions occurring in general practice. Among these must be mentioned tuberculosis and prostatic calculus. When dealing with chronic prostatitis I said that the patient might appear in the consulting room as a case of unexplained epididymitis. The symptoms of the prostatic disease may be so trifling that it is only when an extension occurs along the vas deferens in the direction of the testicle that the patient considers it necessary to consult a doctor. This holds good of a chronic prostatitis that is tuberculous in nature. Pathologists are still divided in their opinion whether genital tuberculosis is centrifugal or centripetal in its spread. In other words, whether it starts in the prostate and extends to the epididymis, or vice versa. Personally, I hold strongly that genital tuberculosis travels in the same direction as other chronic infections of the genital tract, and that in the majority of cases a focus in the epididymis is secondary to one in the prostate or vesicle. One of my reasons for believing this is that in over 60 per cent. of cases both epididymes become involved through time. This fact should be an additional indication for a careful rectal examination in all cases of suspected genital tuberculosis.

The possibility that prostatic symptoms may be due to the existence of one or more small calculi within its substance is sometimes forgotten. The symptoms produced by a stone in the prostate may be similar to those caused by chronic infection or by malignant disease—namely, pain, frequency, and increasing difficulty in micturition. Rectal examination enables the prostatic calculus to be easily distinguished from chronic infection; in the former, an area of stony hardness and, where numerous stones exist, a characteristic grating can usually be detected. The differential diagnosis from a malignant focus is, however, in many cases difficult or even impossible without the help of an *x*-ray examination. Since an *x*-ray of the pelvis is desirable in all cases of malignant prostate, a skiagram will also serve as a means of distinguishing carcinoma from prostatic calculus.

CONCLUSIONS

It will be seen that to the clinician the prostate is an organ of paramount importance. It seems almost that Nature, having handicapped the female by providing her with reproductive organs liable to disease particularly after the menopause, has seen to it that the male should not be unduly favoured, and has provided him with a prostate. Another point brought out is that prostatic lesions may give rise to a wide range of symptoms, and to disturbances of the general health so marked that they throw the primary trouble into shadow. Finally, the moral has been drawn that if we are to avoid mistakes in diagnosis a careful rectal examination, followed, in cases of doubt, by a microscopical investigation of the expressed fluid, must form part of the routine examination of any male patient complaining of symptoms of an obscure nature.

TREATMENT OF PARANASAL SUPPURATION PERSISTING AFTER OPERATION*

BY

PERRY G. GOLDSMITH, C.B.E., M.D., C.M.

PROFESSOR OF OTO-LARYNGOLOGY, UNIVERSITY OF TORONTO; SURGEON-IN-CHIEF OF THE DEPARTMENT OF OTO-LARYNGOLOGY, TORONTO GENERAL HOSPITAL

I am not alone in my view that there has been a great deal of unnecessary and unwise surgical zeal devoted to the nasal accessory sinuses. Eugene Lewis says: "No great amount of clinical experience is required to realize that for some reason or other patients who have been subjected to extensive surgery of the upper respiratory tract are seldom better of their original ills." I commend his courage in demanding less spectacular surgery and more serious consideration of the underlying principles concerned with inflammatory manifestation of mucous membrane. My contribution is merely an effort to discuss the subject from my own practice and experience.

Persistence of discharge from any nasal accessory sinus following operation does not necessarily demand further

* Read in opening a discussion in the Section of Laryngology and Otology at the Annual Meeting of the British Medical Association, Winnipeg, 1930.

surgical measures of a more radical nature. The main symptoms for which the patient sought advice, such as pain or discomfort in the head, nasal or post-nasal discharge, nasal obstruction, recurring head colds, mental depression, or lessening of the power of concentration, may have been so greatly benefited that even if some nasal or sinus secretion persists, it may not be of sufficient importance to require further instrumental intervention.

The extraordinary efforts made to detect the slightest amount of mucoid secretion in an accessory air cell, and the ridiculous weight attached to its presence, are further evidences of the extent to which the subject of foci of infection has clouded our clinical vision and made us forget our elementary physiology. I do not wish to belittle in the slightest a knowledge of the refinements of nasal diagnosis. The use of the endoscope and the exploral suction method of investigating the nature of the inflammatory process in an air cell, as has been so persistently and successfully advocated by P. Watson-Williams for many years, are diagnostic aids of great value.

The type of patient is of importance in determining the most satisfactory treatment in an individual instance. With the neurotic patient, very uneasy if he has any nasal secretion he can dislodge, fearful that by swallowing some of it he is liable to all sorts of diseases, it may simply be necessary to minimize his fears, to encourage him not to worry, and to assure him that there is nothing likely to cause any future trouble. He may well be told that occasional increase of nasal secretion is to be expected when the weather is damp or when he takes "a cold." Regulation of such a patient's manner of living, habits, diet, and exercise is of more importance than local medication.

Persistence of discharge alone from any sinus that has undergone operative treatment is, as a rule, unsatisfactory to the patient and discomfiting to the surgeon. Taking each cavity by itself I shall endeavour to enumerate some of the reasons for failing, in operative treatment, to secure complete relief from undue secretion.

FRONTAL SINUS

Acute frontal sinus inflammation usually gets well of itself, or may require some minor operation, such as removal of the anterior end of the middle turbinate to facilitate drainage. If the discharge persists after this simple operation, it may be helpful to probe or wash out the sinus. The fronto-nasal duct is a very irregular channel surrounded by ethmoidal cells, and in only a very small percentage of cases can it be probed or irrigated without undue traumatism, especially in recent cases of fronto-ethmoidal disease. Following Mosher's method of first breaking into the agger nasi cell, I have been able to reach and irrigate many frontal sinuses, my previous attempts to find the opening of the fronto-nasal duct under the middle turbinated bone having failed. Lavage alone then may be sufficient to cause the disappearance of the suppurative process in the frontal mucosa. Complete cessation of the discharge may not take place. If only a slight amount of mucus comes into the middle meatus, increasing or becoming purulent on slight provocation, and little or no discomfort or systemic symptoms are associated with it, the patient may choose to continue his nasal toilet rather than submit to further operative procedures which in the end may not entirely rid him of his secretion.

This applies to all the sinuses, and I think if we look upon the subject more from the patient's standpoint we will not allow ourselves or the patient to become unduly alarmed by the continuation of some muco-purulent nasal discharge, or be concerned too much because we are able to see some secretion in the washing from the cavity. The finding of lymphocytes or polymorphonuclears, while probably indicating chronicity of the pathological process, should not by itself demand further operative measures. Proetz very aptly puts the question as follows:

> "In such cases is it justifiable to resort to treatment which experience teaches us is useless, simply to do something? Perhaps in occasional instances, but on those occasions certainly the something should be simple, above all, harmless, and not especially expensive."

If the frontal discharge persists and is not associated with any gross ethmoidal disease, some additional measures will be necessary to restore the frontal mucosa to its normal thin moist condition.

The discharge continues owing to the inability of the frontal mucosa to recover from its oedematous condition, due to ineffective drainage. Oedema with some superficial exfoliation of epithelium and marked round-cell infiltration beneath the epithelial layer is the pathological process with which we have to deal. Deficient drainage may be caused by failure to secure sufficient nasal airway prior to operation—by a highly deflected septum, large middle turbinate, or hypertrophy of the anterior lip of the unciform groove.

In the absence of pain, oedema of the forehead, or evidence of bulging of the inferior wall, I believe the best treatment is to wait a little to see the effect of a change in climate; a few dry sunny days frequently make a great difference in clearing up a tardy resolving sinus infection. A few irrigations with a frontal cannula are of considerable assistance. Should the process not respond to such measures it is advisable to try to estimate how much thickening is present, and also gain a knowledge of the size and depth of the frontal cavity. For this purpose lipiodol and *x* rays are very valuable indeed, and help to forecast the future.

The *x*-ray examination may also reveal very considerable ethmoidal disease situated below the frontal sinus, mounding into or even extending over the orbit. In such cases further ethmoidal removal may be most helpful. If the lipiodol examination shows a very greatly thickened mucosa, when all manifestations of acute frontal inflammation have long subsided, I doubt very much if any intranasal measures are likely to be followed by a cure of the mucosal infection. If, however, only a mucoid discharge is present, periodically becoming purulent with acute coryzal attacks, I do not believe that any further surgical measures are necessary. Should pain, oedema of the forehead, or bulging of the upper and inner angle of the orbit occur, some external operation should be considered.

Before any external operation is attempted, a very thorough ethmoidal removal should be performed and a sufficient time allowed to elapse to see the result. In any case of frontal sinus disease requiring external operation there is so much ethmoidal disease present that it is a *sine qua non* that every effort should be made to secure a satisfactory ethmoidal condition before the external operation, or at any rate before the time of the external attack. The late Christian Holmes advocated a small opening into the floor of the frontal sinus in those very acute frontal attacks when intranasal drainage was not obtained. I have on two occasions found it necessary to open an acute frontal sinus through the upper and inner angle of the orbit.

The operation that has given the most satisfactory result, both from the patient's standpoint and from my own, is that advocated by Mr. Howarth (somehow known in the United States as the Lynch operation). If the frontal cavity is moderate in size and not separated into loculi unapproachable through the floor of the sinus, a very satisfactory result will ensue in a large majority of cases. It is essential, however, that all the ethmoidal cells in the floor of the sinus and over the roof of the orbit should be

thrown into one main chamber. Further, a very wide opening into the nose can be obtained by free removal of the inner orbital wall and the ascending process of the superior maxilla. My greatest difficulty is to keep this opening from closing over, and some other method than a large drainage tube or application of silver nitrate seems to be necessary. Denker's method of making a flap to line the new fronto-nasal channel is a very intricate and difficult procedure. I have no experience of it. Professor Seiffert applies a Thiersch graft to a finger-stall packed with gauze and introduced from the anterior nares into the frontal sinus following an external operation on the frontal and ethmoidal cells. I have no experience with this procedure. If the new channel closes over by a diaphragm of connective tissue, or narrows so much by granulations, I resort to the rasp with or without bougie. In the majority of cases this will accomplish the desired result, and the discharge will rapidly subside. When, however, owing to the large size of the frontal sinus and the formation of many partial partitions, the discharge still persists, the surgeon should seriously consider if it is wise to operate further, for the only operation then available is probably associated with considerable scarring. The Killian operation I have given up; the bridge leaves a blind area and often disappears by necrosis. Sewell of San Francisco does not advocate intranasal surgery for the relief of chronic frontal sinus disease.

If a very radical operation is decided upon because of extensive necrosis of the front table, or an acute osteomyelitis is feared or present, a very thorough removal of all the frontal mucosa is essential, no nooks or corners with polypoid material being left, and the cavity being entirely obliterated by allowing the tissue of the forehead to fall into the depression and fill it completely. In large deep cavities involving both sides this is a formidable procedure, and usually results in a cosmetic catastrophe for the patient. Great gentleness in removing the frontal mucosa is essential, lest the bone is nicked and a spreading infective osteomyelitis initiated. Even in cases where there is an extensive fistula in the orbital wall or above the supra-orbital margin, operative procedure, limited to Howarth's operation, may be quite sufficient, but if the fistula is associated with a former Killian operation with necrosis of the bridge, the resulting bone defect will mean a badly scarred forehead.

Failure, then, to cure the suppuration may be due to: (1) insufficient removal of the diseased mucosa; (2) failure to remove all the ethmoidal prolongations about the floor of the frontal sinus and roof of orbit; (3) failure to secure sufficient permanent drainage into the nose; (4) incompleteness of the preliminary ethmoidal removal; (5) failure to recognize suppuration in a large crista galli cell or the opposite frontal sinus; (6) lack of care in ensuring, by occasional large bougie, that the frontal nasal opening is not narrowing too much; (7) too much interference with the healing process in a well-conducted operation, by excessive douching; (8) frequently the operation fails to cure because the operator does not take time to stop all the bleeding and see every step he takes, so that every possible recess and cell is thoroughly opened into the main channel.

SPHENOIDAL SINUS

Persistence of discharge following operation on the sphenoidal air cell is due, in the vast majority of cases, to failure to make a large enough opening in the anterior wall, or failure to keep it from closing or becoming so small that aeration and drainage are not sufficient. The preliminary operative work on the posterior part of the septum and posterior part of the ethmoidal wedge may not have enabled an unimpeded view of the front face of the sphenoid to be obtained. A sufficiently large window may have been made at the operation, but nature succeeds far too often in narrowing the opening by forming a fibrous diaphragm. A large opening may again be obtained by using a strong solution of silver and punch forceps; but there is always a tendency for it to become small later on. The discharge will persist with varying exacerbations, depending on how much infectious oedematous tissue lines the sinus and how readily it drains away. The mucosa cannot be removed by instrumental means, owing to the thinness of the walls separating it from very important structures. I deprecate any efforts made to remove the sphenoidal lining by instrumental means, even if local oedematous (polypoid) areas are seen. The surgeon runs considerable risk in snaring it off, since he is unable to assure himself that a thin plate of bony wall will not come away also; if this separation happens to originate in the superior or external wall a disaster is threatened. It must not be forgotten that the vessels in the submucous layer communicate freely with those of the orbit at the optic foramen, and that in the lateral wall there are many minute foramina leading to the cavernous sinus. There is a venous connexion, also, through the sella turcica.

Some sphenoidal sinuses are very irregular in shape, and have sulci that pass outward and away into the lesser and greater wing of the sphenoid or forward towards the maxillary antrum. In these depressions, as in other sinuses, the mucosa is usually very thick, and even though the greater part of the sinus cavities available for inspection by anterior rhinoscopy are found to be quite healthy, the discharge originating from these inaccessible areas continues.

Irrigations are helpful in removing the secretion from the deeper recesses, and some of the silver salts, such as argyrol or neo-silvol, are decidedly beneficial. Bismuth and oil is sometimes of value in the more recent cases, but has a tendency to cake up and remain indefinitely.

Although I have very little clinical experience to support me, I feel that ionization with zinc in these large irregular sinuses is likely to be a most useful supplementary treatment. With the patient lying on his back, and the chin well turned up, it is a simple matter to keep the zinc solution in the cavity; ionization may be carried out with a long pliable terminal with little difficulty or inconvenience to the patient. The use of strong silver solutions is apt to be followed by very sharp persistent neuralgia, and if there happens to be a dehiscence on the canal covering the vidian, fourth, ophthalmic division of the fifth, or sixth nerve, or of the optic canal itself, serious results may ensue.

Occasionally the sphenoidal sinus has on its upper or external surfaces a large ethmoidal cell, which, having escaped recognition, may be responsible for the persistence of suppuration in the sinus, because it drains into the sphenoid when the patient is lying down.

When the opening persistently becomes too small, owing to the formation of granulations, and ultimately a fibrous sheet, I think it best to allow all inflammatory changes to run their course, and then, when the membranous wall covering the opening has lost most of its blood supply, and is merely a thin layer of fibrous tissue, we may renew our efforts to bite it away without the same liability of the re-formation. Too early and too persistent attempts to destroy this fibrous wall defeat their own object.

The use of Higginson's syringe with a fairly large pipe is a useful instrument for a patient's use in douching forcibly the posterior region of the nasal cavity. An acute sphenoidal suppuration may exist as a separate disease, and rapidly responds to simple drainage, but the discharge occurring in chronic cases is so often associated with disease of the posterior ethmoidal cells that the success of the treatment of the sphenoidal suppuration depends on our ability to cure the disease in the bordering

air cells. It must always be remembered that the outer two-thirds of the front face of the sphenoid forms a common wall with the last posterior ethmoidal cell. The opening into the sphenoidal sinus may therefore be made much larger by removal of this common wall, even if the last posterior ethmoidal cell is healthy and has to be sacrificed. Occasionally there is a partition dividing the maxillary antrum into an anterior and posterior compartment. Suppuration in the posterior part may simulate disease of the posterior ethmoidal cell or the sphenoidal sinus. The sphenoidal septum may deviate so much to one side that the same sphenoid can be entered from either nostril. I have had one such case.

MAXILLARY ANTRUM

A not uncommon cause of persistent discharge from an antrum that has been operated upon by any method is failure to recognize frontal and ethmoidal disease. The discharge from a suppurating frontal sinus may empty directly into the maxillary antrum, or, owing to a large ethmoidal bulla or a prominent anterior lip of the unciform groove, be directed easily into the antrum. Reduction of these obstructions with removal of the anterior end of the middle turbinate may be all that is necessary to secure a satisfactory result in the antrum.

The intranasal operations for drainage of the maxillary sinus have not, on the whole, given me satisfactory results, except in cases of comparatively recent duration, or what might be termed long-drawn-out acute inflammation. I have found it difficult to secure a large enough opening, especially where the nasal wall bulges into the antrum. A sufficient amount of bone may have been removed, but it does not follow that the thick mucous and fibrous wall is removed in as complete a manner. In many cases where I have opened the canine fossa in patients on whom I have performed intranasal drainage, I have been greatly surprised at the smallness of the opening leading into the inferior nasal meatus and its poor situation. There is no comparison between the thoroughness with which the operator can remove the nasal wall of the inferior nasal meatus in a canine fossa operation and in one through the nose. In the former he can see every step he takes, while in the latter he can only hope for the best.

It is advisable in all cases, I feel sure, to remove the anterior third of the inferior turbinate. Measures directed to preserve this structure frequently prevent the patient washing out the antrum and lessen the value of ventilation. It is curious how some operators persist in thinking that they can thoroughly remove the polypoid oedematous tissue in the antrum by using various curved curettes passed into the intranasal opening. Periscopic magnifying lights introduced into the antrum may give a very exaggerated idea of the oedematous change present.

Operations, such as advocated by Canfield, in which the antrum is entered at the anterior nasal angle give a better approach and permit a direct though small view. Instrumentation may then be carried out, but not in as thorough a manner as I believe should be done.

Failure, then, in these antrum operations has occurred because the operation was unsuitable to the pathological condition causing the discharge—that is, the oedematous change does not respond to simple aeration and drainage. The canine fossa or Caldwell-Luc operation was designed to secure a better approach to the diseased tissue and to obtain more accurate and complete intranasal communication. Removal of diseased tissue was then carried out by direct inspection with various shaped curettes. A marked advance in clearing up antral suppuration followed, but complete cessation of discharge did not by any means ensue. The causes of the persistence of the discharge or its reappearance on slight provocation is due, I am quite sure, to the method of attacking the antral mucosa. Operations performed under general anaesthesia, with the patient lying down, simply mean scraping out the antrum very imperfectly in a sea of blood. Since I have had my patients in a half-sitting position and have peeled out the mucosa in these chronic oedematous cases I have had very much better results. The intranasal openings are made very large, as large as the inferior nasal meatus permits. I endeavour to separate the membrane from the antrum wall until it is attached only at the ostium area, where a slight twist brings the whole mass away, just as a pudding bag is taken out of a pot. In this manner one does not miss the thick pyogenic mucosa in the pre-lacrymal recess, anterior alveolar fossa, or sphenoidal fossa. Further, one is able to observe very accurately the condition of the floor of the antrum and see that carious areas are not permitted to remain associated with suspicious or crowned teeth. It is then also very easy to bite away some of the membranous wall of the middle meatus.

General anaesthesia is not necessary in all cases. Preliminary use of morphine and hyoscine with cocaine pledgets in the outer wall of the nasal meatuses gives very satisfactory anaesthesia. I have carried out bilateral operations many times on females in quite a satisfactory way. It is the method of election in cases of chronic pulmonary conditions. My main contention is that failure to cure the discharge is due to insufficient removal of the diseased mucosa. It is all very well to say one should remove only the diseased mucosa, but how can one say that the comparatively thin lining seen to-day is not many times thicker if viewed at another time? I believe the antral mucosa under slight provocation swells up like a sponge. In my preliminary examination of these antral cases I use lipiodol and olive oil, 1 in 3, and it is surprising how much the *x*-ray picture differs from that found even two weeks following the injection. It is easy, however, for the lipiodol to escape from the antrum during the journey to the *x*-ray department or owing to the dependent position in which the ostium is placed while the plate is being taken. When this occurs it is very easy to be misled as to the amount of thickened mucosa. A mixture of bismuth and liquid paraffin is retained much more readily in the antrum, gives quite as good a shadow, but is difficult to remove even by irrigation. Some beneficial therapeutic value is found when bismuth is used, and even if some remains permanently in the antrum it is not a matter of much consequence. Hunt of London, Canada, advocates the removal of all the mucosa that can be stripped off by blunt dissection. This I think applies to those cases where the oedema and polypoid hypertrophy have not reached such a stage as to involve all the mucosa, and is a commendable effort to be conservatorily radical.

The opening in the nose should be flush with the floor of the antrum, and I think it probably better to lay down a flap so as to lessen the tendency to granulation on the antro-nasal crest. A complete peeling out of the mucosa may not be followed by cessation of discharge, because somehow a membranous curtain has re-formed another antro-nasal wall in the inferior meatus. I have seen this occur in cases where I have felt that my intranasal opening was too large and I have been unnecessarily zealous. I cannot explain this, but I feel that inefficient removal of the anterior part of the turbinate is a factor as well as possibly my failure to use a flap on the antro-nasal ridge. Persistent and forcible douching of the antrum following operation procedures delays the healing and regenerative process that McGregor and Knowleton

have shown takes place after complete evisceration of the antral mucosa. A very foul odour with copious purulent discharge sometimes comes on several days after the operation. It does not last long, and responds readily to monsol and saline irrigations. A piece of packing, a sponge, or a loose piece of bone or tooth is very easily left in, and readily accounts for persistent discharge. If in the removal of the antral mucosa sharp instruments are used, damage to the bone may follow, and areas of granulation tissue with bony necrosis may result and keep up the secretion.

The reparative process in the antral cavity following complete evacuation of the membrane may take a curious course. Discomfort, discharge, even odour with or without crusts, may persist or recur at intervals. Difficulty may be experienced in inserting the curved cannula, and when this state of affairs is found some months after the canine fossa operation, a reasonable inference seems to be that the antro-nasal wall has re-formed. But one may be very easily misled. Experience strengthens my advocacy of reopening antra where persistence of discharge is considered due to a local condition, such as the formation of webs of diaphragms resulting in recesses where retention of secretion easily takes place. Where odour is associated with secretion I think that this procedure is especially advisable.

Assuming that an antrum has been thoroughly cleared of all pyogenic oedematous mucosa and an efficient opening made into the nose, it may be months before all noticeable secretion ceases. Many things may interfere with the reparative process, and this applies to all the other sinuses as well. The patient may have poor recuperative powers owing to ill-health produced by anaemia, tuberculosis, syphilis, chronic nephritis, or any debilitating disease. His manner of living, habits, diet, even the atmosphere in which he works, may have a bearing. The heavy, rapid, immoderate eater and with chronic intestinal sepsis and constipation, clear up well after sinus operations. Lack of and confinement indoors has a definite influence, Canada the excessive heat and dryness of living ments conduces to permanent nasal and sinus con- Extremes of temperature and humidity add terially to the readiness with which oedema of appears. Cold and dampness of the feet have ency to alter very promptly the turgescence of the mucous membrane, as was first shown by Muecke. as many of our patients with oedematous manifesta- ions of their sinus mucosa have as an underlying factor an allergic state, failure to overcome the hypersensitive- ness leads to a persistence of secretion, even though a new mucosal lining forms and is well aerated, because this new tissue still reacts to the same irritant. A family history of allergic manifestations, the presence of positive skin tests and excessive eosinophils in the nasal secretion and the blood, suggests a consideration of allergy as the underlying cause of the oedematous mucosa. Such mucosal reactions do not necessarily come under the classification of infective processes, but the soil is such that acute or chronic infection readily occurs and persists with purulent discharge added to the mucoid material already present. Hansel goes so far as to say:

"Many of the chronic empyemas undoubtedly follow in the wake of an allergic process in which an oedema of the mucosa has occurred. In the non-suppurative hyperplastic or catarrhal group of paranasal sinus disease, clinical and histopathological studies have proven that in the great majority of cases the process is primarily an allergic disease. Therefore, all hyperplastic, non-suppurative sinus diseases should be considered as of allergic origin until proven otherwise."

Allergy may then dominate the picture and may explain those factors that lead some writers to speak of an oedematous diathesis just as we speak of eczema, asthma, or even gall-gladder disease.

THE ETHMOIDAL LABYRINTH

Happy is the surgeon who thinks he has solved the ethmoidal problem, but happier still is he whose patients agree with him. I approach the subject of persistence of suppuration following operations on the ethmoid with much misgiving. Owing to the unusual situation, being within the nose yet partially surrounded by the remaining accessory nasal air cells and without any uniform anatomical formation, inflammatory processes associated with discharge present diagnostic and therapeutic problems that give the surgeon much cause for worry and oftentimes lead him into difficulties where his surgical judgement is put to the severest of tests. Persistence of discharge following operations on the ethmoidal cells is probably the commonest symptom present.

The persistence of suppuration following operations on the ethmoid is in most cases due to failure in providing free, spontaneous, and permanent drainage to those cells whose inflamed oedematous mucosal lining is responsible for the secretion of the discharge. Mosher has made the way into the ethmoid simple, but it remains for someone else to show how to complete the work easily, after this stage has been reached. It may, however, have been quite sufficient to open the ethmoid from the agger to the front face of the sphenoid, and by breaking through the floor to secure free ventilation and drainage, the middle turbinate being left to the last, as it is an excellent landmark to keep us from the cribriform area. The middle turbinate overhang may then be removed. Pratt, however, prefers to leave this in place. The ease with which infection can reach the meninges along the nerve sheath, as shown by Logan Turner, is probably the most outstanding contribution to the pathology of nasal sinus infection in our time. Removal of the whole middle turbinate, and all the ethmoidal cells that can be reached in one sweep, after the manner of Ballinger and Sluder, is an extraordinarily bold procedure, and one not without serious risk to the patient. I do not use this method. It is anatomically impossible to remove all the ethmoidal cells by the intranasal route. In my own practice, when I have decided to remove all the ethmoidal cells I am able to reach safely through the nose, I prefer to proceed in stages and allow sufficient time to elapse between such operations, so that most of the inflammatory oedema has had time to subside. I can then orient myself much better and follow the discharge more directly to its source. Nothing must induce the surgeon to hurry, and, if he is in doubt as to the safety of his manipulations, or fails to see what he is doing all the time, it is better to stop at once, and on some future occasion, maybe a month or more, complete the procedure. When I have cleared out the ethmoidal areas as thoroughly as I can, I allow the patient to douche out his nose for a month or more before doing anything further. He may then be so much relieved that further treatment is not desired; but if there is still suppuration I try to determine if I have overlooked any hidden cells, and also estimate as accurately as I can how much of the ethmoidal disease is dependent on the disease of other nasal air cells.

Suppuration high up in the nose following a thorough cleaning out of the ethmoid cells intranasally is probably due to diseased ethmoid cells running out over the orbit and unapproachable by any intranasal measures. The frontal mucosa may or may not be involved, but, if so, it is not likely to be restored to normal unless the infected ethmoidal cells about its floor are removed.

If the nasal discharge is associated with the formation of multiple nasal polypi, recurring high up in the nose after removal, and the *x* rays show orbital prolongation of the ethmoid, the question of an external approach to this area is to be considered.

If any further operative treatment is thought desirable, I am strongly of the opinion that this should be carried out by external measures, for in this way one can determine the condition of the frontal mucosa and can remove under direct vision all the higher ethmoidal prolongations with little risk to the patient. It is not, however, free from danger, for I have had one fatality, when a very slight leaking of cerebro-spinal fluid was followed, even ten days later, by meningitis. Probably when the ethmoid has been operated upon a number of times, and a mass of polypoid and scar tissue is left, through which purulent material trickles, and all recognizable landmarks have been removed, the surgeon is faced with very considerable responsibility. He must assure himself as to the condition of the other nasal air cells and their probable influence on the present ethmoidal condition. If the sinuses have been to a large degree eliminated and another attempt to clear up the ethmoid area is to be carried out, certain preliminary proceedings are desirable. The more room gained in the approach to the upper and posterior regions of the nasal meatuses, the greater the chance of success, for the surgeon sees and knows better what is being done. Even a moderately deflected septum may be resected with advantage ; Skillern points out the benefit obtained by removal of the uncinate process from its insertion to its end. By this measure a gain of one-quarter to three-eighths of an inch in width is obtained—quite enough to make the difference between success and failure. When so much of intranasal mucous membrane as follows extensive ethmoidal operations has been removed, it is surprising how little crusting ensues.

THIRTY YEARS OF STOMACH SURGERY*

BY

JAMES PHILLIPS, F.R.C.S.ED.

CONSULTING SURGEON TO BRADFORD ROYAL INFIRMARY AND TO BINGLEY HOSPITAL

In 1898 Osler published a volume of clinical lectures on abdominal tumours, fully one-third of which was devoted to tumours of the stomach. He described eighteen cases. Of these three were operated on by Mr. Halsted ; all of them were of the " forlorn hope " variety. Thus of one patient Osler says: " As the case was a desperate one and the man's condition hopeless, the election of operation was left to the patient." Mr. Halsted resected a pyloric growth, but the emaciated patient died two days later.

Early in the new century there was a boom in abdominal surgery. Gastro-enterostomy and other forms of operation on the stomach began to be performed quite regularly, so that in 1905 Moynihan had gathered sufficient material to enable him to publish his first book on the surgical treatment of gastric and duodenal ulcer.

PATHOLOGY OF STRUCTURE AND FUNCTION

There is little difference between the gastro-enterostomy performed twenty years ago and that of to-day, but our ideas of pathology have undergone radical change. In the early days attention was paid chiefly to mechanical difficulties ; to-day we put stress on disorders of function. Then the surgeon was concerning himself with anatomical pathology ; now physiological pathology is believed to be of greatest importance. For example, the condition known as " hour-glass stomach " has practically disappeared as a clinical entity. The radiographer of thirty years ago would develop, from time to time, an *x*-ray photograph of a stomach showing a constriction dividing it into two compartments. It was presumed that an organic stenosis was present, which made it difficult for stomach contents to pass from the proximal pocket into the distal pocket. And gastro-gastrostomy—the construction of a large opening between the two compartments—was the operation usually performed in such cases. We now know that the stenosis is only apparent, and that the narrowing was essentially due to localized spasm of the stomach muscles at a point corresponding to an ulcer on the lesser curvature. The radiographer has ceased to report cases of hour-glass stomach, and the operation of gastro-gastrostomy has fallen into disuse.

Similarly, if an *x*-ray examination revealed the stomach dilated and dropped, it was presumed that the dropped stomach must find it difficult to empty its contents uphill over the held-up arch of the duodenum, and various ingenious operations were devised to overcome this mechanical difficulty. Gastroplication was a method of taking tucks in the big stomach in order to reduce its size. In gastropexy a series of stitches was used to shorten the gastro-hepatic omentum, and so to raise the stomach to a higher level in the abdomen. The great omentum was sometimes stitched to the anterior abdominal wall above the level of the navel in order to make a shelf on which the stomach should rest. In many cases gastro-enterostomy was performed on patients who suffered from gastroptosis in order that a large stoma should be made at the most dependent part of the big stomach through which, it was presumed, the stomach contents would drop by force of gravity into the jejunum. Indeed, that splendid surgeon Mayo Robson, in his book on diseases of the stomach, suggested gastro-enterostomy as the rational treatment for acute paralytic dilatation of the stomach. We have learned by bitter experience that the pathology of the dilated stomach is functional and not mechanical, and that the onward progress of food from stomach to bowel is always the result of peristaltic muscular action, and never due to the force of gravity. A dropped atonic stomach remained flabby, and failed to function normally, even when a large opening had been made in the most dependent part of its greater curvature. Surgeons discovered to their dismay that an occasional complication of gastro-enterostomy, the very operation which Robson had suggested as treatment for this condition, was paralytic dilatation of the stomach.

ACUTE PARALYTIC GASTRIC DILATATION

Over twenty years ago I had my first experience of acute dilatation of the stomach.

A youth had been at a football match on a very cold Saturday afternoon. He came home feeling famished with cold and hunger, and bolted a big, indigestible meal, along with a large quantity of tea. He became ill in the night, with abdominal pain and vomiting. The doctor who was called to see him on Sunday morning found him looking gravely ill, and sent him to the infirmary with a diagnosis of fulminating appendicitis. When I saw him I thought the case was more probably one of duodenal perforation. On opening the abdomen I found the cavity almost entirely filled by an extraordinarily dilated stomach. A stomach tube was passed and an attempt to empty the stomach by siphonage and manipulation was imperfectly successful. I followed this by injections of strychnine, but the stomach showed no sign of contracting. After the patient had been put back to bed I remembered how in my student days the " Saturday-night drunks " had been given apomorphine, and how this drug had made the drunken man vomit " as if."

* A paper read at a meeting of the Bradford Medico-Chirurgical Society.

in the words of an irreverent fellow student, "he was going to bring up his immortal soul"; so apomorphine was given to my poor patient, but without avail. Toxic secretions were poured out into his paralysed stomach, and in a few hours he died, cold and blue and pulseless.

Long ago I realized that I had treated this young man on quite wrong lines. His was a very extreme case, and, in my opinion, the patient would have died whatever treatment he received. Less severe cases, however, can be saved when treated on rational lines.

For example, a man, enfeebled by suppurating gunshot wounds, shared with his ward mates a supper of bacon and beans provided by a good-hearted orderly medical officer. A few hours later I was asked to see him. He was complaining of severe abdominal pain, and had vomited undigested food. When the emaciated abdomen was exposed the outline of the greatly distended stomach, bulging forward in the upper part, was at once apparent. The stomach was immediately washed out, the process being repeated every few hours in order to get rid of the highly toxic materials which were being secreted into the paralysed organ. No food was given by the mouth for some few days, but several pints of saline fluid were injected daily into the cellular tissues of the armpits. After five or six days the stomach regained its power to contract and the patient recovered.

The condition may be likened to the paralysis of the bladder following childbirth or operations about the perineum, of which we have probably all had experience. The method of treatment should be similar in both conditions. When a puerperal woman develops retention of urine we neither make a dependent opening in her bladder nor do we expect to make her bladder contract by giving her strychnine or pituitrin. We arrange for the periodical emptying of the bladder by the catheter, and hopefully await the natural restoration of contractible function.

STOMACH PARALYSIS COMPLICATING GASTRO-ENTEROSTOMY

As I have already mentioned, some degree of gastric paralysis may follow the performance of a gastro-enterostomy, and it may become a most alarming complication. The patient may have made quite satisfactory progress for a few days; then loss of appetite occurs, and either a copious vomit of dark green fluid, or, more commonly, constant nausea and frequent vomiting of small quantities. Sometimes, but by no means always, a succussion splash is obtainable. Recently treatment of this alarming complication has been facilitated by the introduction of Jutte's tube. This is a 4-foot-long rubber tube of less than 1/4 inch diameter; it is passed through the nose into the stomach, which is thus emptied by continuous siphonage. The tube causes the minimum of discomfort, and can if necessary be left in position for several days. It has the enormous advantage over the stomach tube that the thirsty patient may drink water as freely as he likes. The water siphons back through the tube, so that the patient at the same time as he is satisfying his thirst is also effectively washing his stomach.

ACUTE DROPPED STOMACH

In 1922 Barclay published the results of a series of *x*-ray experiments on patients whose stomachs were presumably normal. These investigations demonstrated how rapidly the position and state of the stomach could be made to alter by nervous and mental stimuli. He cited a number of cases. While a woman was being screened in the dark, a noise was made by dropping a heavy weight behind her, and with the fright her stomach was seen quite suddenly to drop from a normal position to that of pronounced dropped stomach. Conversely, he observed the stomach of a brewer's drayman contract when the man was informed that he was going to have a bottle of beer. Barclay made the suggestion that the sinking sensation felt in the epigastrium, say, by a medical student going in for an examination, is probably due to actual physical sagging of the stomach, and later observers have found that the stomachs of examinees were lying lower and were more dilated than when they were again screened after the examination.

EFFECT OF GASTRO-ENTEROSTOMY IN PEPTIC ULCER

With the exception of the rare case in which a cancer or an oedematous ulcer is producing extreme mechanical stenosis of the pylorus, we no longer regard the beneficial result of a gastro-enterostomy as being due to the construction of a dependent opening which permits food to leave the stomach easily. In some way, by no means fully understood, the flooding of the stomach with alkaline jejunal contents appears to be the all-important factor in producing the healing of a peptic ulcer. In common with many other surgeons, I have more than once performed a preliminary gastro-enterostomy for a condition which looked like a pyloric cancer, and on opening the abdomen a second time, perhaps only ten days later, with the intention of resecting the growth, have been pleasantly surprised to find the induration gone and little or no evidence of what must have been an active ulcer surrounded by inflammatory oedema. Those of us who have been operating for a good many years have learned that the local removal of a gastric ulcer is likely to be followed by recurrence unless by gastro-enterostomy or some other method the stomach contents are kept alkaline after the excision operation, whereas we have cases of gastric ulcer which have been cured and have remained healed when a gastro-enterostomy only has been done, the ulcer being left untouched. In view of the possibility of cancer developing on the site of a gastric ulcer it must always be desirable to get rid of the ulcer—by the cautery, by local excision, by sleeve resection, or by partial gastrectomy—whenever this can be done without grave risk to the patient; but I have followed up cases of gastric ulcer which I treated twenty years ago, or more, by gastro-enterostomy alone, and I know that the patients remain quite well.

THE ATTACKS ON GASTRO-ENTEROSTOMY

During the past few years gastro-enterostomy has been subjected to attacks from opposite camps. On one side, some surgeons have claimed that the operation is not sufficiently radical, and, on the other side, some physicians have been teaching that medical treatment has practically done away with the need of operation for ulcer. A number of keen surgeons, almost all of them in the junior ranks, have insisted that the ulcer-bearing area should be excised in every case of either gastric or duodenal ulcer. As I have said, I agree that where its position and condition make it safe to do so, a gastric ulcer is better excised, not because it is unlikely to heal after a simple gastro-enterostomy, but because the ulcer base may contain cells which are liable to become cancerous. No such liability has been found to exist in duodenal ulcers, and gastro-enterostomy results in the cure of these in so high a percentage of cases that I agree with the late Mr. Basil Hall, who said that to advise duodenectomy for the cure of a duodenal ulcer was rather like advising amputation of the limb for the cure of a varicose ulcer of the leg. The attack from the physicians' side is much more plausible. If you cure an ulcer, they say, by an operation which keeps the stomach contents alkaline, why operate? Why not give alkalis by the mouth? Frankly, however appealing and logical this argument may be, it can only be accepted with many limitations.

In the first place, it is not only the making of the gastric contents alkaline which apparently is essential for the curing of an ulcer, but the keeping of the contents alkaline—a very difficult matter. For the patient of leisure who can get specially prepared meals at short intervals, and who has the means and the mind to persevere with alkalis taken persistently over a period which may extend for a year or even longer, I am prepared to believe that medical treatment is likely to result in a cure. One pitfall is that, even without treatment, symptoms in a case of duodenal ulcer may clear up for months on end, only to return when the patient has begun to congratulate himself that he is permanently cured. Similar remission of symptoms following alkaline treatment must not be regarded as necessarily meaning that the ulcer is cured finally and for ever. I wonder what proportion of patients possess the temperament which will allow them to bend their minds continuously to give anxious attention to their health, to refrain from eating or drinking anything forbidden, to give up smoking, to take medicine (alkalis, olive oil, etc.), and to go on doing all these things, day in and day out, over a period of at least many months. We all know that, however willing a patient may be to do this, the working-class man or woman, and those in many other walks of life, must find it quite impossible to carry out such a regime satisfactorily.

For example, I was asked to operate on a patient last year. I found an unhealthy appendix, a gall-bladder containing stones, and a small ulcer on the front of the first part of the duodenum. I removed the appendix and gall-bladder and gladly agreed to the physician's suggestion that medical treatment should be tried for the small ulcer. This was carried out for six weeks in hospital, and for a time after the patient went home; but when he went back to work, he found it impossible to continue the treatment rigidly. He was an intelligent man, doing a foreman's work, and he assured me that he did the best he could. While at work one day he had a big melaena, and about six months after the first operation, I operated again, and successfully did a gastro-enterostomy. The ulcer was found active at this second operation.

STATISTICS OF STOMACH OPERATIONS

I have prepared the statistics of all my stomach operations performed at the Bingley Hospital during the years 1920–29. I have chosen the Bingley figures rather than those of the Bradford Royal Infirmary because I have myself done all the operations at Bingley and taken the notes, and chiefly because it has been possible to follow up every case.

There were in all 87 patients operated on. Of these 53 had gastro-enterostomy performed (3 for inoperable cancer, 6 for gastric ulcer, and 44 for duodenal ulcer). In the same period, however, 22 operations were performed for perforations of ulcers—20 duodenal and 2 gastric. In other words, 25 per cent. of all the stomach operations were for perforations. Most of the patients who "perforated" were known to have ulcers, were taking alkaline medicines, and had been advised to take a modified diet.

ALKALINE TREATMENT AND THE ARTISAN

However ideal medical treatment of chronic peptic ulcer may be in theory, it is practically impossible for the man who has to earn his living in the open market to carry out effectively the regime laid down by the advocates of medical treatment; circumstances make it a sheer impossibility for him to do it, however sincerely he may wish to treat himself correctly. By contrast, of the 38 patients who were treated by gastro-enterostomy and who are still alive, and residing in the neighbourhood of Bingley, I am told by their doctors that every one is able to do his or her work; 7 still require occasional treatment, the other 31 are reported to be "well" or "very well."

A further point with regard to the claim for surgical treatment in cases of peptic ulcer is illustrated by the following:

I operated six weeks ago on a man who had a dyspeptic history lasting many years. Recently symptoms had become more persistent and rather more severe, and so at last he was driven to submit to operation. We found not only a very obvious duodenal ulcer, but also a very unhealthy appendix. This is a very frequent coincidence.

The point I wish to emphasize is that whatever may be done by medicine to cure a duodenal ulcer, even the most enthusiastic advocate of medical treatment of ulcer will not claim that alkaline medication will make a diseased appendix healthy. Diet and drug the patient as you may, the little vermiform test tube goes on manufacturing its toxins and pouring them into the patient's tissues.

Last year I operated on a man who had had a gastro-enterostomy performed a dozen years ago by another surgeon. Symptoms and *x*-ray examination suggested the presence of a jejunal ulcer. I opened the abdomen and found the gastro-enterostomy opening in splendid condition. I removed the appendix; the dyspeptic trouble disappeared soon after and has not recurred.

GASTRIC CANCER

There are two quite distinct types of gastric growth—the cancer which develops at the site of a chronic peptic ulcer, and the cancer which arises *de novo* in the stomach. The symptoms of gastric ulcer are not nearly so characteristic as those of duodenal ulcer. I am sure that many a patient, usually female, who has been treated, perhaps for a number of years, by her doctor for chronic dyspepsia, and because of the indefiniteness and variation of her symptoms has very possibly come to be regarded as a "hopeless neurotic," would, if *x*-rayed, be found to have a chronic gastric ulcer. When a gastric ulcer has been diagnosed, the possibility of malignancy supervening should be an additional reason for suggesting operation.

The *ab initio* cancer symptoms are quite different. Rather sudden loss of appetite is the commonest. When a patient comes complaining that he has no relish for his food, and is losing weight and strength, an *x*-ray examination should be advised without delay. If cancer is present, a "filling defect" in the stomach outline will be found, more often than not, to make the diagnosis clear. In only a small proportion of these cases is radical removal of the growth possible; in the majority of the operated cases, metastases will kill the patient in less than two years. All the cases are not fatal, however, and I know of quite a number of patients who are alive and well years after a gastrectomy for cancer confirmed by the microscope. These "cures," however infrequent, encourage the surgeon to attempt radical operations for these otherwise hopeless cases.

SUMMARY

To summarize very briefly the lessons learned from thirty years' experience of stomach surgery:

1. The pathology which is important in most stomach lesions is functional and not mechanical—a disorder not of anatomy but of physiology.

2. A stomach whose vagus and sympathetic nerve supply is normal will empty itself whether the patient is lying or sitting or standing, or even standing on his head;

gravity plays a negligible part in the emptying of the organ.

3. Acute dilatation of the stomach is a paralytic condition analogous to retention of urine and requiring treatment on similar lines.

4. Acute paralytic dilatation may come on idiopathically, but more usually as a post-operative complication—at times of gastro-enterostomy or partial gastrectomy.

5. There is reason to believe that the cure of peptic ulcer after gastro-enterostomy is due to the continuous neutralization of the gastric acidity which the operation ensures.

6. In many cases treatment of ulcer by diet and alkalis is likely to fail because the patient either cannot or will not submit to a sufficiently prolonged and thorough course of treatment.

7. Of a hospital series of stomach operations, 25 per cent. were for ulcer perforations; most of these patients had had medical treatment.

8. If a diseased appendix is present along with an ulcer there is little likelihood of the ulcer being cured by medical treatment alone.

9. Many cases of chronic gastric ulcer fail to be diagnosed because the symptoms are apt to be both variable and ill defined; *x*-ray examination is desirable in most cases of chronic dyspepsia.

10. Sudden loss of appetite in a patient whose digestion has previously been normal is highly suggestive of stomach growth; an *x*-ray examination should be advised without delay in such cases.

MUSCLE EXTRACT TREATMENT OF SOME GRAVE VASCULAR DISEASES

BY

M. S. SCHWARTZMAN, M.B.

A suggestion was made by me in two previous papers[1,2] to apply in "intermittent claudication" a new method of treatment with injections of muscle extract, the therapeutic value of which in angina pectoris was discovered by Professor J. S. Schwartzman (Odessa)[3,4] and confirmed by a number of authors on the Continent.[5] The object of the present paper is to give a short account of the results obtained in a larger number of cases of vascular diseases of various types. On account of space I shall confine myself to a brief description of three illustrative cases and a summary of the results obtained in forty-two other cases, reserving the details for future publication. The two cases first described were demonstrated before the Clinical Section of the Royal Society of Medicine on February 13th, 1931.

THROMBO-ANGIITIS OBLITERANS WITH ADVANCED GANGRENE

History.—A mechanic, aged 42, with no history of venereal disease, but who had been smoking ten cigarettes a day, complained that since 1924 he had felt pain in his calves on walking. Trophic disorders appeared on the toes and dorsum of the right foot in 1926. Gangrene developed in 1929, when his right leg was amputated, first below the knee (Mr. C. Price Thomas at Westminster Hospital), and soon after above the knee (Mr. Tudor Edwards). At the operation the right popliteal artery was found to be thrombosed. In December, 1929, gangrenous changes appeared on the left big toe. In January, 1930, a periarterial sympathectomy of both left femoral and anterior tibial arteries was performed (Mr. E. Rock Carling). After a short period of relief the condition became gradually worse, and the patient was readmitted to the Westminster Hospital in July, 1930.

Examination.—The left leg, foot, and toes were stone cold, deeply blue, and oedematous. The soft tissues of the big toe were black, sloughing, and hanging in shreds. There was a very offensive discharge from underneath the slough. A black area extended alongside the bases of the toes; no inflammatory reaction was noticeable. The patient suffered such excruciating pain that he threatened to commit suicide. The dorsalis pedis and posterior tibial arteries were pulseless. The angle of circulatory sufficiency was about 70 degrees. The amputation stump of the right thigh ulcerated over a large area. The Wassermann reaction was negative; blood pressure was 135/90.

Treatment.—Treatment with daily injections of muscle extract was started by me on July 5th, and continued till August 9th at the Westminster Hospital (under Mr. E. Rock Carling), and later at the London Jewish Hospital (under Mr. S. I. Levy) till the middle of October. At first the soft tissues of the big toe and at a later date the distal $1\frac{1}{2}$ phalanges separated. The pain and swelling disappeared, the discharge stopped, the leg and foot became normally warm, and the wounds healed up. Neither elevation nor dependent position caused any pain. Return of colour was prompt at horizontal position. Blood pressure fell to 125/70. The arteries were pulseless as before treatment, and no change in oscillometric index could be detected.

The case terminated in spontaneous amputation of a part of the big toe, instead of a high amputation above the knee, which was thought to be indicated before the commencement of this treatment.

COMBINED THROMBO-ANGIITIS OBLITERANS AND RAYNAUD'S DISEASE

History.—A miner, aged 43, with no history of venereal disease, complained that for nine years he had had pain in his legs after walking a distance of about a hundred yards. A few months later he developed attacks of blanching of all his fingers and toes, followed each time by an intensely blue colour and associated with a severe burning sensation. The affected parts became persistently swollen, cold, and cyanotic, and within a few months the tips of eight fingers, and all the toes except one, fell off. The burning sensation became unbearable in December, 1929, when black offensive discharging ulcers appeared on the stumps of the self-amputated parts. The patient slept badly and was almost cachectic in appearance. He was admitted to the Guest Hospital at Dudley on June 11th, 1930 (Dr. G. Walker).

Examination.—The posterior tibial and dorsalis pedis arteries were imperceptible on both sides. The right radial artery could be felt, but not the left. *Postural colour* changes were very slight. The blood pressure was 130/100. *X*-ray examination revealed necrotic changes at the terminal phalanges of fingers and toes. No calcification of arteries was seen.

Treatment.—Treatment with muscle extract was begun on June 15th. Four days later the patient stated that the pain was less severe, and that he could sleep better. After twenty injections the patient slept without hypnotics. A second course was started on July 5th, and continued daily for a month.

The following is an abstract from the hospital notes sent to me by the house-surgeon, Dr. Browne, on August 10th: "All pain is gone except occasional spasms at the bases of the great toes, which are not quite healed. The feet and hands are normal in colour and sensation. The face is rosy and fattened, and the patient is better than he has been for years."

The patient is under my observation at present at the London Jewish Hospital. The pain has never recurred, the gangrenous patches have been replaced by healthy granulations, there is no discharge, and skin is growing over the wounds from the edges. The blood pressure fell to 110/60.

Of two other cases of thrombo-angiitis obliterans with advanced gangrene, the treatment in one resulted

in cessation of pain and complete healing up of the gangrenous patches ; in the other further development of gangrene was arrested, but the pain did not stop in spite of three months' treatment, and the patient was admitted to a hospital with a view to amputation.

Of nineteen cases where there were no gangrenous changes, but where intermittent claudication was the chief complaint, five of them being due to thrombo-angiitis obliterans and fourteen to arterio-sclerotic occlusion, the results were satisfactory in sixteen. The ability to walk without pain or tiredness in the legs increased in some of them from a distance of twenty to thirty yards to two miles ; in others from one hundred to two hundred yards to a mile and over. Some of the patients have been under observation for another six months, the improvement being still maintained ; only in three cases, of which two had treatment for a short period, was no improvement noticed. On the whole, cases of thrombo-angiitis obliterans responded more quickly than those of arterio-sclerotic occlusion. On analysing the results the conclusion reached was that the rapidity of the response to treatment was proportionate to the amount and severity of the vasomotor phenomena. The more prominent the spastic factor in a given case, the quicker and more striking are the results of this treatment.

DIABETIC GANGRENE

Taking into consideration that diabetic gangrene is primarily due to impoverished nutrition resulting from athero-arterio-sclerotic obliteration, I felt justified in trying the same treatment in diabetic gangrene. The following is a brief description of one of three cases treated.

History.—A woman, aged 66, was admitted to the London Jewish Hospital on July 3rd, 1930, with a history of diabetes diagnosed two years previously, and with gangrene of the left fourth toe of three months' duration.

Examination.—The heart was enlarged ; the second aortic sound was markedly accentuated ; there were emphysematous changes in the lungs ; the abdomen was negative. Both feet were cold and bluish. Posterior tibial and dorsalis pedis arteries were pulseless on both sides. The left fourth toe was persistently cyanotic. A discharging sinus was seen at its base. This appeared about three months before admission. Urine was acid, having a specific gravity of 1030 ; albumin was *nil* ; sugar was present ; acetone was *nil*. Blood sugar on fasting stomach was 306 mg. per cent. Wassermann reaction was negative. Radiograms of both legs showed calcified arteries. Blood pressure was 175/110. Local treatment, radiant heat, and rest for two months had no effect.

Treatment.—Daily injections of muscle extract were started on July 5th, 1930, and continued for about a month. On the eighth day the feet became warmer, the colour improved, and the pain disappeared. On the twelfth day the sinus stopped discharging. In three weeks after the commencement of treatment the sinus healed up. The feet were almost of normal colour and temperature. Blood pressure fell to 140/90. The patient was discharged from the hospital, but treatment was continued for another two months three times a week. No insulin or any other treatment was given. At the hospital the patient received the same diet as she had before admission.

In two other cases the results were equally satisfactory, insulin being simultaneously administered in one of them.

ANGINA PECTORIS

Apart from thrombo-angiitis obliterans, arterio-sclerotic obliteration, Raynaud's disease, chronic asphyxia, and diabetic gangrene, treatment with muscle extract was applied by me in nineteen cases of angina pectoris, in eleven of which there was a history of coronary thrombosis and evidence of myocardial disease. Nine patients showed striking improvement, which manifested itself in complete cessation of pain or sensation of constriction on exertion. Some of the patients have been under observation for over a year. No recurrence has been noticed. In three cases the pain recurred, but a few more injections sufficed to ameliorate the condition. In four cases the treatment resulted in a definite improvement, but the patients still complained of occasional pain on walking after meals. In one case of great severity in which cervical sympathectomy had failed, the treatment was followed by a considerable improvement at first, but this was maintained only for three weeks, after which the previous condition recurred, and there was no response to further treatment. In two cases the treatment failed altogether.

REMARKS

A great deal of research has still to be done to elucidate the rationale of this method and the nature of the active principle. It is clinically evident, and confirmed by the physiological experiment, that the extract acts as a powerful depressor. It is most probably by overcoming the vascular spasm, which seems to be an important additional factor even in organic vascular diseases, that the extract partly produces its therapeutic results. The same depressor effect may account to a great extent for its beneficial action in angina pectoris. In our experiments both alcoholic and aqueous protein-free extracts of skeletal muscle of young animals (calves) were used.

There are no doubt present, particularly in an active muscle, some substances (? metabolites) which are partly responsible for the increased blood supply required for exercise. It is likely that these substances form the active principle of the muscle extract. Not much can be said yet about their chemical nature. The extract contains but very little histamine, if any. The substances are not identical with choline, and the depressor action is not counteracted by atropine. They may contain adenosine, as was recently suggested,[6 7] but physiological experiments indicate that they are not likely to be identical with it.

Apart from their central vaso-dilatant action they seem to have also a local vaso-dilatant effect, as some of my clinical experiments tend to show. On this observation and on a technique of treatment of peripheral vascular diseases based on it, I hope to be able to report in the near future.

The investigation has been carried out chiefly with the original extract kindly supplied by Professor J. S. Schwartzman (myol 111). In a few cases an extract prepared by G. Henning of Berlin (myoston) was used. Experiments are being conducted with a view to standardizing the preparation, increasing its potency, and elucidating some problems, such as method of sterilization, concentration, etc., which are still unsettled.

I wish to express my gratitude to Professor J. S. Schwartzman of Odessa, of whose original discovery this research is a further development, and to Sir James Purves-Stewart for the encouragement he has given me. The work has been chiefly carried out at the Westminster and London Jewish Hospitals, and I am greatly indebted to Mr. E. Rock Carling, Mr. G. T. Mullally, Dr. A. Abrahams, Mr. S. I. Levy, Dr. D. Krestin, Dr. G. Konstam, and Dr. N. Pines, for allowing me to treat some of their patients.

A CASE OF LIPOID NEPHROSIS

BY

E. A. LUMLEY, *M.C.*, M.B., B.CH., D.P.H.

SQUADRON LEADER R.A.F.M.S.

The clinical and chemical criteria required to support the diagnosis of lipoid nephrosis as described by Muller, Epstein, and others are as follows: marked oedema and proteinuria (with cylindruria and lipoiduria but no haematuria), oliguria, lipaemia (hypercholesterolaemia), decreased blood proteins with alteration of the albumin-globulin ratio, decreased basal metabolism, no nitrogen retention, and normal or insignificant rise of blood pressure.

The details of the case described below comply with the majority of the conditions specified. One or two omissions of relatively minor importance are explained by the fact that the patient was attended at her home, the distance from the laboratory making it difficult to carry out as systematic an investigation as I would wish.

REPORT OF CASE

Mrs. B., aged 26, consulted me for swelling of the feet and legs, which had been coming on gradually for six weeks. Apart from a certain amount of local discomfort there had been no malaise or acute illness during or prior to that period. Except for slight pallor she looked and felt perfectly well, and was, in fact, induced by friends to seek medical advice. The patient has one child, aged 2½ years; the pregnancy and puerperium were normal, the urine, examined during the later months of pregnancy, revealed no abnormality. The history, therefore, is entirely negative.

On examination, no septic focus was detected in the mouth or throat, the teeth and tonsils being in perfect condition. Abdominal and gynaecological examinations were also negative. There was marked oedema of the feet and legs, pitting being demonstrable to the upper extremities of the tibiae, but none elsewhere. The heart was normal as to size, sounds, etc.; radial and brachial arteries were soft and of moderate tension; blood pressure was 125/88 (in subsequent examinations the systolic pressure has varied between 122 and 128). There was no evidence of fluid in the pleural or peritoneal cavities.

The first twenty-four-hour specimen of urine collected measured 700 c.cm., with specific gravity 1025, and gave a heavy cloud on boiling with dilute acetic acid.

The case was treated on general principles until further investigation could be made—namely, rest in bed, reduction of protein and salt in the diet, with a mild diuretic and diaphoretic mixture. Moderate diuresis occurred, and the oedema was considerably reduced after five days, the patient being then allowed up on condition that she rested for two hours in the afternoons.

In the meantime the volume of the urine had increased to 1,000 c.cm. per twenty-four hours; albumin, estimated on two occasions by Esbach's albuminometer, was 0.5 and 1 per cent. Microscopical examination of the centrifuged deposit failed to reveal any casts or erythrocytes, this being a constant finding up to the present (the seventh week of observation), with the exception of a recent examination, when "a very few granular casts" were reported, blood still being absent. During the first five weeks a moderate number of refractile fatty globules were constantly present in the deposit. The absence of casts and blood, and the severe albuminuria found in the preliminary examination of the urine, coupled with the marked oedema and moderate blood pressure, led me to suspect that I might be dealing with an example of the syndrome of nephrosis, and, accordingly, certain determinations in blood chemistry were carried out.

Biochemical Examinations of Blood and Urine

Blood cholesterol estimated in the first and second weeks of observation was present to the extent of 296 and 300 mg. per cent. respectively, with blood urea 32; urea in the urine at this time varied between 2 and 3 per cent. (These early estimations were carried out mainly with a view to a provisional diagnosis, and the determination of whether there was nitrogen retention or not, in order that a high protein diet could be instituted as soon as possible if a low urea figure indicated that course.)

A more complete analysis of blood and urine was carried out later (sixth week), the patient having then been on the special diet for three weeks. The results were as follows:

Blood.—In 100 c.cm. the total protein was 6.1 grams, urea 34 mg., albumin 3.91 grams, non-protein nitrogen 30 mg., globulin 2.19 grams, cholesterol 226 mg.

Urine.—Specific gravity was 1023. Total protein was 10.4 grams, albumin 8.9 grams, and globulin 1.5 grams per litre. No sugar, pus, or blood was found. A very few granular casts and a few epithelial cells were present in the deposit, but there were no erythrocytes or lipoid droplets.

Progress of Case

On being allowed up at the end of the first week, the patient still had slight oedema of the legs, and in addition some swelling of the hands in the morning, which, however, usually passed off during the course of the day. Epstein's diet, rich in protein, with low fat and moderate restriction of carbohydrate, was commenced during the third week, the amount of fluid per day being limited to one and a half to two pints. The daily amount of urine, which increased up to 1,000 c.cm. at the end of the first week, estimated on various occasions since, has been 1,100 to 1,200, which may be considered about normal, considering the fluid intake. The oedema of legs and hands, which still persisted when the special diet was instituted, has now (seventh week) completely cleared up. It may be stated that, with the exception of occasional aperients, no drug, diuretic, or tonic was prescribed from the end of the first week up to the date of the last blood analysis. A course of thyroid extract has, however, now been commenced. The patient, never particularly ill at any time, appears to be in a very fair state of health, in spite of the drain of protein in the urine, amounting to 11 or 12 grams per diem.

The case is presented with the suggestion that it probably might be included in the group of chronic nephrosis.

Laboratory examinations were kindly carried out by Wing Commander H. E. Whittingham and Flight Lieutenant Hugh Corner of the Royal Air Force Medical Service.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

TRAUMATIC CLEFT PALATE: MICROCOCCUS CATARRHALIS MENINGITIS: RECOVERY

Micrococcus catarrhalis meningitis is rare in children. Its victims usually find their way into the post-mortem room. The following exception from the surgical ward of the East London Hospital for Children is worth recording.

M. H., a girl aged 5½ years, was admitted on June 17th, 1930, with an astonishing history. A stable door had fallen off its hinges on top of the child, and one of the spikes had pierced the roof of her mouth. She was pale, bleeding profusely from nose and mouth, and yelling lustily. There was no haemorrhage from the ears, but considerable effusion of blood had taken place into the soft tissues of the eyelids and beneath the conjunctivae. The palate was split in the mid-line as far forward as the alveolar margin, which was itself intact. With the exception of a few bruises the face had escaped injury. There was no escape of cerebro-spinal fluid from nose, mouth, or ears. The child became considerably shocked, and the pulse for more than twenty-four hours continued in the neighbourhood of 140 to the minute. On the following day she was drowsy and irritable, with marked photophobia and retraction of the head and neck. There was no delirium or vomiting. Kernig's sign was positive. The temperature rose to 102° F. Lumbar puncture yielded a turbid fluid under pressure, which contained more than 20,000 polynuclear leucocytes per c.mm. The protein was raised to 180 mg. per 100 c.cm. No organisms were seen in the smears, and there was no growth on cooked blood in forty-eight hours. Polyvalent antistreptococcal serum (20 c.cm.) was given intravenously, as it was thought, in view of the nature of the injury, that the streptococcus was responsible for the meningitis. The patient continued to be dangerously ill, and lumbar puncture was repeated on the following two days, when

10 c.cm of anti-scarlet fever serum were injected intravenously and 10 c.cm. intrathecally. Cerebro-spinal fluid obtained on the fourth day of illness grew *Micrococcus catarrhalis* in twenty-four hours on serum agar with haemolysed blood.

The child made a rapid and uninterrupted recovery. The temperature by the fifth day had come down to normal. The cerebro-spinal fluid three weeks after the accident was free from cells and organisms, with a normal protein value, and by that time the cleft in the palate had soundly healed. The patient was discharged a week later to the hospital's convalescent home, and change of air completely restored her health. There was no alteration in the mentality.

I wish to thank Mr. E. T. C. Milligan for permission to publish the notes of this case, and Dr. F. Temple Grey for the pathological investigations.

W. R. BETT, M.R.C.S., L.R.C.P.,
Late House-Surgeon, East London Hospital for Children.

Reports of Societies

PREVENTION AND TREATMENT OF DRUG ADDICTION

The Section of Psychiatry of the Royal Society of Medicine and the Society for the Study of Inebriety held a combined meeting on March 10th for a discussion on "The prevention and treatment of drug addiction." Dr. S. A. KINNIER WILSON presided.

Types of Addicts

Dr. WILLIAM BROWN, in opening, said that there were various causes of drug addiction, and upon the cause at work depended the method to be selected for prevention and later on for treatment. He distinguished four classes of addicts: (1) those who had become victims to the drug habit through the necessity of taking drugs in illness or for the prevention of pain or production of sleep; (2) those who had taken to drugs because of a deep-seated tendency to strive for some new experience; (3) those who had recourse to a drug in order to increase their efficiency in work which was important to them; (4) a nondescript class. As far as the first of these classes was concerned, prevention should be directed to the medical trouble, the underlying cause, insomnia, or whatever it might be. In the second class (to which, according to American figures, 90 per cent. of addicts belonged) recourse must be made to prevention of access. In the third class the hope must be placed in national and international measures for prevention of the drug traffic. In the fourth, the methods of prevention would vary with the circumstances, but would have the general character of sympathetic investigation of the cases, and would make use of whatever psychological methods might be brought forward to help in the fight against the vice. Some physical methods of treatment were indispensable in all but the slightest cases, and generally residence was necessary in a special home, where the individual could be disintoxicated in gradual stages; whatever the physical method, however, the psychological aspect was of great importance. Many of these patients thought that morphine would remove their depression for the time being, until eventually they were at the mercy of the drug. Hypnotism was justified if the person could be hypnotized; in other words, failure of hypnotic treatment meant always failure to hypnotize. But hypnotism alone was insufficient; the psychological treatment had to go deeper, and in every case analysis was necessary. Any kind of treatment should involve a certain amount of analysis, and, when time allowed, a long analysis should be carried out with a view to getting at the causes of addiction, raising the patient's hopes, and enabling him really to desire something other than the pleasure or relief of the drug. The speaker had found that so-called suggestion treatment and training in auto-suggestion was really a training of the will, and in this connexion he related his own personal experience with a very mild drug—namely, tobacco. He had always over-smoked; he had given it up at various times, but on returning to the habit had smoked as heavily as ever. He decided to try the method of self-suggestion. One evening he burned his pipe and his tobacco, relaxed his muscles, became thoroughly passive, and thought to himself, "I shall never smoke again; smoking is not a part of my universe any more." He went to sleep that night, and woke up next morning without any thought or feeling about tobacco. That was four years ago, and since then he had never had any sense of deprivation. The making of that one affirmation to himself was sufficient to save him from any neurasthenic feelings whatever. Although that could be called a method of self-suggestion, it was really a method of completing the act of will. It was a resolution, but a resolution carried out more definitely than under ordinary circumstances, and for that reason the symptoms disappeared completely. Although he had used the word "analysis" he wished some other word could be discovered for describing this method of taking the patient over his past and getting him to face the consequences of events in his life; in short, to know himself, and not only to know himself, but to act upon his knowledge.

International Control

Dr. E. MAPOTHER said that the problem of drug addiction in this country was a very simple matter. Despite the extreme vigilance of the police, the Home Office knew the names of only 250 addicts in England, and probably the real number was not much greater. The personal experience of any one clinician who did not definitely specialize must consist of a very limited number of cases. His own experience consisted of 25 cases, of which 15 were in Maudsley, 4 in mental hospitals, and half a dozen outside. The cure of addiction was, of course, the task of the doctor. In the majority of cases it was rather a hopeless task if the word "cure" was regarded in the sense of permanence; prevention was the better way. Dr. Mapother went on to speak of the international supervision of the drug traffic. Up to date the evidence of the development of an international conscience was a little disappointing. There had been no success with regard to any ideally simple method of limitation. In the case of cocaine it was hoped that since its legitimate use was wholly external, it might be possible to get a similar drug or derivative which would be equally effective as a local anaesthetic, and not have the exhilarating action of cocaine, but unfortunately this had been found impossible. For anaesthesia by subcutaneous infiltration some substitutes were equally good, but for anaesthesia obtained by painting on the surface there was nothing which would take the place of cocaine, and therefore its abolition was unthinkable. In the case of opium and morphine the difficulties were not those of pharmacology, but of politics. Turkey, Persia, and Russia had refused to co-operate in regulating the drug traffic at all or to reduce the profit which their nationals derived from its exploitation. The legitimate international traffic was directed through the League of Nations by a system of licences which would be effective if it were loyally operated in all countries. In this matter, at all events, England was one of the model countries of the world. The amount of smuggling into this country was negligible, and there was very little of that use of cocaine among the "demi-monde" or in the underworld which was apt at times to figure luridly in the "yellow" press. The amount of definitely illicit supply of either cocaine or morphine by chemists or doctors to patients was very small indeed. Allowance had to be made, of course, for the tolerated supply given to certain addicts who could not exist without it. The cocaine habit was hardly ever

acquired as the result of medical treatment; it was a vice contracted by those who had access to the material, such as nurses, doctors, or druggists. On the other hand, addiction to morphine or heroin was very largely the result of medical treatment. In other words, the starting-point for the taking of cocaine was, in the majority of cases, the attempt to induce pleasure, and the starting-point for the taking of morphine was the attempt to reduce displeasure of pain. He had not noticed—and he was sure it was not correct—that any considerable proportion of psychasthenics had any tendency to take drugs. The sort of people who took them were of the "spoilt child" type, who could not forgo immediate gratification of any impulse. They were the same sort of people who were sexually promiscuous, and that was the reason for the frequency of drug-taking amongst prostitutes, and amongst those who engaged light-heartedly in adultery.

Physical Treatment of Addiction

Dr. MACDONALD CRITCHLEY dealt with the physical treatment of drug addiction. Although it was admitted that the cure undoubtedly rested with psychotherapy, physical methods had a place. When a victim first came under observation he might be too debilitated physically to react to psychotherapy, and physical methods, empirical or irrational as they might be, often did valuable spade-work. Withdrawal of the drug was obviously the first duty, and the clinical picture was soon complicated by "withdrawal symptoms." He outlined the diverse cures and regimens which had been advocated at various times. The oldest of these comprised the use of sedatives in very large doses. The hyoscine cure consisted of the administration at hourly or half-hourly intervals of hyoscine hydrobromide until forty or sixty doses had been given. A state of hyoscine intoxication supervened, with delirium, dilated pupils, etc.; after this delirium had been maintained for twenty-four to forty-eight hours, injections of pilocarpine were given until the physiological effect was reached. The rest of the cure consisted in the counteraction of the pilocarpine poisoning. Within the last few months there had been advocated an insulin cure for morphine and other drug addiction. For the first six or eight days after complete withdrawal of morphine, up to eighty units of insulin were given in the twenty-four hours. Various other more or less vague therapeutic measures had been advocated from time to time; a group of Americans had gone on the principle that the withdrawal symptoms did not result from intoxication by unneutralized antibodies, but were due rather to a general lack of function of the endocrines, and had based their treatment on that hypothesis, claiming very good results.

Fatigue and its Importance in Morphinism

Dr. F. G. LAUGHTON SCOTT said that from his own experience of the drug addict he thought that those who took a drug to improve their output of work were probably as important and numerous as all the other classes of addicts put together. He was in daily contact with members of the medical profession who, under special stress, had taken a drug, and had then continued it for its stimulant and not for its narcotic effect. The stimulant effect of morphine had not been sufficiently considered. The truer picture of the majority of English addicts was of men who did not "run away from life," but had come to need a special type of stimulation before they could meet life successfully. The narcotic effect of morphine eventually passed away, and left behind the stimulating effect. It was instructive to look upon morphine habituation as a chronic pathological need for a special type of stimulant, and not for a special narcotic. That being so, it was important at every stage of treatment to consider the effects of fatigue very carefully, to spare the addict fatigue as far as possible, and educate him out of the undue fatigability which was part and parcel of his recovering state. The speaker went on to give a few facts with regard to the use of belladonna or some derivative, which was used in nearly all the American methods of withdrawal. The only use to which this substance was applied ordinarily was to make the patient more or less violently delirious, and delirium was one of the things to be avoided. But belladonna might have other uses. A very small dose acted as a vagal stimulant. If the tolerance to belladonna was very gradually and carefully increased, the primary and central stimulant action on the vagus was retained, so that eventually enormous doses of belladonna—as much as $2\frac{1}{2}$ ounces in twelve hours—could be given while the patient remained quiet and his heart rate was slightly slower. This use of belladonna enabled that drug to take over the stimulant action on the vagus which was normally exercised by the patient's morphine, and the shock of sudden deprivation of the stimulant was considerably modified by having an effective agent which would keep the vagal preponderance. At any rate, he had found in practice that the furious bursts of sympathetic overaction were greatly modified, and in some cases even abolished.

Psycho-analysis

Dr. EDWARD GLOVER spoke of the therapeutic value of psycho-analysis in this connexion, and mentioned reasons why, in his opinion, extra-psychological therapy seemed rather devoid of strategic value. The psycho-analyst held that too great importance was attached to the physiological aspects of habit formation. The violent reactions which occurred during deprivation were not strictly comparable with the results of laboratory experiments. In true drug addiction the importance of the drug was primarily psychological. Drug addiction, though apparently monosymptomatic, could be regarded as a compound capable of being split up into simple constituents, and the radical cure was obtained through such a splitting up. Certain factors, such as symbolism, elicited by psycho-analysis enabled the psycho-analyst to estimate the depth of the treatment required. He was beginning to suspect that many drug addicts were in part inverted paranoiacs, the difference being that in such cases the addict was persecutor and persecuted in one. In the superficial sense addiction could be prevented, but to chase a symptom or to withhold access to a drug was not necessarily to cure a disease. He confessed himself dissatisfied with his own earlier attempts at treatment. It was comparatively easy to reduce a habit, by analysis alone, from huge to minimal doses, but the inevitable result in the resolution of most addictions was the outcrop of hysteria or of the obsessional state. It was on the analysis of these underlying psychotic tendencies that the success of any psycho-analytical treatment of addiction depended. Nevertheless, he thought that the psychological riddle of addiction might be solved sooner than a cautious pessimism permitted them to hope.

Dr. MURDO MACKENZIE asked whether one was going to approach the study of drug addiction as a diagnosis or as a symptom. There were two types of addiction which had come within his personal experience; one type had used the syringe, and the other had not. The first type had been frankly depressants, the others largely schizophrenics. The latter included those addicted to alcohol. He felt himself that all that could be postulated about drug addiction was fundamental instability, and when that had been done it was necessary to make a diagnosis of the individual who was being dealt with. A generalized therapy could not apply to different psychological types. Dr. C. W. BRASHER considered that the Home Office had underestimated the number of addicts in this country.

Dr. KINNIER WILSON, in summing up the discussion, said that no definition had been given of what constituted drug addiction. John Hunter took a teaspoonful of laudanum before every one of his lectures, but no one would dream of calling him an addict; yet if some other infinitely more humble individual did it he might not escape that name. The natives of Bolivia chewed the coco leaf, and were worse labourers without it. He mentioned a case known to him in which two nurses, at the age of 24, had each taken a quarter of a grain of morphine as an experiment. One of them was violently sick, and never took it again. The other girl started to take it, and took it continuously for forty years. At 64, when he saw her, she had got into obvious difficulties connected with obtaining supplies of the drug (she had never taken more than two grains), and after he had "cured" her she wrote and asked him which was her real life; to her the normal life was the one she had been living for forty years, and the abnormal life was her life without the drug. He thought they should proceed warily in regard to condemning drug addicts before satisfying themselves as to what standard they were going to take for diagnosis. He was entirely convinced as to the smallness of numbers of addicts in this country. On his private list he found that he had treated twenty-five patients, of whom less than 50 per cent. were members of the medical profession. He had "cured" all but one of the twenty-five cases, though he used the word "cure" not in the scientific sense, or as Dr. Glover would insist upon it. In some cases the cure was maintained, others came back for another "cure" every year. He thought it perfectly legitimate to treat symptoms, especially with the superficial and comparatively innocuous type of case that one might get. He had used the hyoscine method, but never to the extent mentioned by Dr. Critchley.

Dr. WILLIAM BROWN, in replying, defined an addict as one who became more and more under the influence of the drug, needing larger doses of it, and becoming more degenerated and disintegrated in character. He thought that Dr. Glover underestimated the amount of analysis done by those who did not call themselves psychoanalysts. In reply to Lady Horsley, he said his method of self-suggestion found an admirable scope in the treatment of alcoholics.

ANAESTHESIA IN CHILDBIRTH

At a meeting of the Liverpool Medical Institution held on February 12th, with the president, Professor W. BLAIR BELL, in the chair, Mr. J. ST. GEORGE WILSON read a paper on anaesthesia in childbirth.

He began by saying that recently there had been various suggestions as to the best anaesthetics in childbirth. He was of the opinion that an attempt should be made to obtain the use of the voluntary muscles of expulsion; thus some form of local or regional anaesthetic was indicated. His favourite was one which was injected extradurally into the sacral canal. Describing the technique, Mr. Wilson said that injection was made through the sacral notch at the lower end of the canal, by means of a short needle inserted for not more than two inches, following the method described by Dr. Evans (*Lancet*, December 6th, 1930) in treatment of sciatica. The anaesthetic used was 40 c.cm. of freshly prepared 1.5 per cent. novocain; percaine and 1 per cent. planocaine were not so satisfactory. The method produced anaesthesia of the vagina and vulva, with retention of "bearing-down" efforts, but not the abolition of sacral pains of labour. Relaxation of the perineum was not marked. The anaesthesia lasted 1½ hours. In primiparae injection should be made when the head was beginning to distend the perineum, and in multiparae when the cervix was fully dilated. Forceps deliveries, manipulation of breech with extended legs, and repairs of the perineum could be carried out without other anaesthetic. Induction was easy, and could be done by nurses.

In the discussion which followed, the president said that any attempt to simplify the administration of anaesthesia during parturition was worthy of the most serious consideration. At the present time there was a campaign for the provision and insistence of anaesthesia in all labours. This, of course, could not be maintained on scientific grounds; it was a sociological sentiment, which was justified in so far that whenever there was no contraindication the pain of labour should be prevented. The ideal single anaesthetic for labour had still to be discovered; it should be one that did not interfere with the muscular contractions of the uterus, yet allayed all pain. Further, it should have no harmful effect on the mother or child; it should be easy of administration and amenable to control. It did not seem likely that all these attributes could be possessed by one substance. A mixed method, such as local perineal anaesthesia to relax the muscles of the pelvic floor and to make that region insensitive, with a drug to abolish painful impressions without interfering with uterine contractions, would to a great extent meet the demands.

Dr. C. ALLAN BIRCH said that in view of the fact that the presence of the foetal head on the perineum normally caused strong expulsive contractions at the end of the second stage, one would expect some delay in the birth of the head in cases in which the perineum had been rendered anaesthetic.

Dr. M. DATNOW remarked that the method introduced by Mr. Wilson appealed to him, especially as one could manage without an anaesthetist. He had frequently used spinocain in operative midwifery, and had found it satisfactory. It did not interfere with the uterine contractions, there was a considerable diminution in the amount of bleeding, and if combined with scopolamine it gave a good anaesthesia with very little subsequent discomfort to the patient. Dr. R. J. MINNITT said that he thought there was a large field of research possible in this direction. He had had some experience of gas and oxygen anaesthesia in midwifery, and believed that the higher percentages of gas with rebreathing, while producing unconsciousness, tended to stimulate the pains of labour.

IMMUNIZATION AGAINST DIPHTHERIA AND SCARLET FEVER

Dr. C. O. STALLYBRASS read a paper on immunization against diphtheria and scarlet fever. He pointed out that while hospitalization of cases had greatly diminished the prevalence of several diseases, this result had not followed in the case of scarlet fever and diphtheria. Following the introduction of an antitoxin, the death rate from diphtheria and scarlet fever had been greatly reduced. In Liverpool it had now become common to inoculate simultaneously against the two diseases.

After quoting figures to show the efficiency of these measures, Dr. Stallybrass detailed his own experience of immunization against scarlet fever and diphtheria in institutions in Liverpool. Not only could outbreaks of these diseases in orphanages and similar institutions be rapidly brought to an end, but it was noticeable that where fresh entrants to the institution had been tested or immunized, they remained free from these diseases. It was pointed out that as two-thirds of the deaths from diphtheria and scarlet fever occurred under the age of 5 years, immunization should be carried out preferably about the second year of life. Fortunately this was the time of life when reactions as a result of inoculation rarely occurred. Such reactions were, however, not infrequent in adults.

In the discussion which followed, Dr. HUBERT ARMSTRONG expressed the opinion that errors of technique

were an inadequate explanation of occasional failures, both of the Schick test response and of the inoculations to produce immunity. He instanced two young adults who had developed diphtheria shortly after negative Schick tests (with controls), and two others who had contracted the disease, one three months and the other six months after a full course of immunizing injections. He was confident that the general results were dependable, and he had been impressed by the complete stamping out of diphtheria in the Bluecoat Hospital by these means during the last five years. Dr. C. RUNDLE thought the dosage quoted by Dr. Stallybrass was on the conservative side, and had been considerably exceeded in America. Dr. A. E. HODGSON said that the routine active immunization of the nursing staff of the City Hospitals, Fazakerley, against scarlet fever was instituted in June, 1926; since then only three nurses had developed the disease. In the twelve months prior to that date eleven nurses contracted scarlet fever in the course of their duties, and of these one died. Active immunization of the nursing staff against diphtheria was commenced in January, 1929, and no case had occurred since.

TREATMENT OF PITUITARY DISORDERS

At a meeting of the Brighton and Sussex Medico-Chirurgical Society, held on March 5th, with the president, Mr. H. NETHERSOLE FLETCHER, in the chair, Dr. FLORENCE EDMONDS read a paper on some disorders of the pituitary body, and their treatment.

Dr. Edmonds began by giving a short account of the development of the pituitary body, followed by a brief survey of its histology. In dealing with the physiology of the gland, she said that the secretion of the anterior lobe was known to contain three hormones, and probably a fourth; the two most important were the secretion affecting growth and the gonadal stimulating secretion. The female sex hormone had been obtained in crystalline form from the urine of pregnancy, and Collip had obtained the same product from the placenta. The secretion of the posterior lobe had two constituents—namely, vasopressin and oxytocin. The effects of these were irregular, but exerted a certain influence similar to pituitrin. The secretion of the posterior lobe was shown to have the following properties: a stimulant to plain muscle, oxytocic, pigmentary, and galactagogue actions, influence on the excretion of water, and on fat and sugar metabolism. The work of Cushing tended to show that the important centres which had to do with primitive instincts were situated in the diencephalon, and were controlled by the extract of the hypophysis (the diencephalon and hypophysis being connected by a nerve tract); and that for normal working the diencephalon, nerve tract, and hypophysis must all be intact. Dr. Edmonds briefly stated the signs and symptoms of pituitary disease, drawing special attention to disorders of the reproductive syste to adiposity, and to pituitary headache. She described the affections of the anterior and posterior lobes, and onditions of under-action of both lobes. Acromegaly a d pituitary gigantism tended to be self-limiting, but in most cases hyperpituitarism was followed, sooner or later, by pituitary insufficiency.

Cushing had emphasized the importance of early diagnosis; a Wassermann tes t should be done in every case of pituitary insufficienc y in order to rule out syphilitic basilar meningitis or gumma. All children who showed retarded bodily and sexual development, especially if associated with headache and polyuria, should be considered as suffe ring from pituitary insufficiency until proved other wise. The treatment of pituitary disorders depended up on a careful estimate of the pathological condition. If a umours were stationary or regressive no treatment was indicated. If progressive, they should be operated on in the early stages before the surrounding structures had suffered much injury. The treatment of pituitary disorders not due to tumour formation varied according to the activity of the gland. If hyperactive and causing symptoms, exposure to *x* rays might be helpful. If hypoactive, the active principle of the lobe or lobes involved should be administered, either orally or hypodermically. The preparations for oral administration were disappointing in their effects, although many clinicians claimed to have had good results. It was found that whole gland pituitary extract was more efficacious than that of a single lobe, and if combined with thyroid extract its effect was increased. Hypodermic administration of posterior lobe extract was now being used, the physiological dose being determined by the vascular, the intestinal, and the general reactions. The intestinal reaction was considered the index of the maximum dose; this should not be exceeded. Ordinarily, one or two injections of the amount which elicits the intestinal reaction were given weekly.

INJECTION TREATMENT OF HAEMORRHOIDS, PRURITUS ANI, AND FISSURE

At a meeting of the Sheffield Medico-Chirurgical Society on February 18th, with the president, Professor GRAHAM SIMPSON, in the chair, Mr. W. J. LYTLE read a paper on the injection treatment of haemorrhoids, pruritus ani, and fissure.

Mr. Lytle said that in spite of the good and lasting results of operations for the cure of haemorrhoids, the method of treatment by injection with sclerosing fluids was being employed with increasing frequency. In addition to its safety, the advantages of the treatment were that it required neither anaesthetic nor confinement to bed, and it caused no pain. The solution which had given the best results was 5 per cent. carbolic acid in almond oil, as suggested by Albright and Blanchard. This solution was preferable to the older 20 per cent. carbolic acid in glycerin. The injections were most conveniently made in the left lateral position by the aid of McEvedy's lighted speculum; 3 to 5 c.cm. of the solution was injected into the submucosa, well above the level of three selected piles. At this level the mucous membrane was insensitive to pain. Two subsequent injections were made at weekly intervals, each of which was below the level of the previous one. Simple uncomplicated internal piles should be selected for treatment by this method. Those which were prolapsed and thrombosed or were complicated by fissure in ano were unsuitable for injections. The immediate results were excellent. All symptoms disappeared after the first or second injection. It was too early to speak of the final results, but by means of a follow-up system he was enabled to say that they appeared to be permanent. There were no complications to be feared except ulceration, which resulted from inadvertently injecting the solution into, instead of beneath, the mucous membrane.

Mr. Lytle also described the treatment of fissure in ano and pruritus ani by the injection of anaesthesin benzyl alcohol and ether or percaine in oil as suggested by Gabriel. For anal fissure Mr. Lytle advised injections of from 2 to 5 c.cm. into the sphincter. This produced a relaxation of the muscle which allowed the fissure to heal. If a sentinel tag was present it should be removed. In deeply undermined fissures operative treatment was necessary because, although symptoms were relieved by injection, the fissure would not heal owing to the fact that the parts were not at rest. In cases of pruritus ani which failed to respond to other methods he had found that the injection of these anaesthetic solutions into the subcutaneous tissues around the anus were often very beneficial.

Reviews

RECENT ADVANCES IN FORENSIC MEDICINE

Recent Advances in Forensic Medicine,[1] by Professors SYDNEY SMITH and JOHN GLAISTER, deals with the diagnosis of firearm injuries, the identification of firearms, powders, projectiles, and cartridges; the examination of hairs; precipitin tests; blood grouping; the estimation of carbon monoxide in the blood and of alcohol in the blood and urine; the detection of metals by the spectroscope; and the use of ultra-violet light in the examination of pictures, forgeries, and other objects. This list covers a wide range, and while some of the subjects lie outside the scope of forensic medicine their extreme interest and (as the authors point out) the difficulty of obtaining information elsewhere justify their inclusion.

The opening chapters include the identification of firearms, a part of criminal investigation which is of particular interest in view of the evidence given in the recent Gutteridge murder trial; the description is very full, and should be of great value to anyone investigating this subject. The excellent chapters on hairs and the precipitin test are also very welcome as a ready means of reference, because these examinations are only briefly dealt with in ordinary textbooks. Blood grouping and carbon monoxide poisoning are becoming subjects of increasing practical importance. Of the first a good description is given, but in the account of the latter the reader will be disappointed; the problems arising daily in medico-legal practice as a result of recent advances are not discussed, the material being confined to a description of the quantitative estimation of carbon monoxide in the blood. Mention is made of the tannic acid method of Henderson and Haggart, but it is to be regretted that the modification of this test by Sayers, Yant, and Jones of the U.S.A. Bureau of Mines, which is of practical value to those engaged in coroner's work, is not described. The method of detection of nitroxyhaemoglobin and its importance (*British Medical Journal*, August 1st, 1925, p. 187) might also have been included with advantage. Strong efforts have been made in the last few years to gain recognition for the estimation of alcohol in the blood and urine as an index of intoxication, and we note with interest that the authors are of opinion that this estimation cannot be relied upon to give the desired result.

The subject-matter of the book is most excellently presented and well illustrated, and everyone engaged in the practice of medical jurisprudence should possess a copy. Though a description of expert laboratory methods, the book is so written that it will appeal to all medical men, and even the layman will find much to interest him.

POST-ENCEPHALITIS

In the compilation of the fourth series of neurological studies[2] Dr. GUILLAIN has been associated with Dr. TH. ALAJOUANINE. The periodic publication of these studies is an event of interest to all neurologists, and in this series the joint authors have recorded some of the observations made at the neurological clinic of the Salpêtrière since the publication of the third series in 1929. Four of the eight sections into which the volume is divided are devoted to clinical pictures illustrating various pathological conditions with which different parts of the brain, spinal cord, and the peripheral nerves may be affected.

Of particular interest, in view of the epidemic nature of the disease, the kaleidoscopic character of its clinical manifestations, and the consequent difficulty in making a diagnosis in sporadic cases, is the section dealing with the Parkinsonian syndrome and other features of post-encephalitis. Thus, two cases of epidemic encephalitis are described in which myasthenia became the predominant feature, a progressive condition more serious than the fatigue and weakness which are commonly associated with this form of encephalitis, and to be distinguished by electrical tests from bulbo-spinal myasthenia. The next case described is that of a Parkinsonian patient aged 42, illustrating the rapidity with which deformities may develop in the upper and lower limbs. Here the contractures occurred in both hands and both feet and in the order in which these limbs were severally affected with previous Parkinsonian rigidity. An interesting and well-illustrated account is given of the case of a boy of 12, in whom the onset of Parkinsonism was followed by a condition of general hypertonus, resulting in torsion spasms and abnormal attitudes. The authors note that the lordosis, rotation of the head, flexure of the arms, varo-equinus, and other abnormal postures assumed by this patient are suggestive of the experimental condition of decerebrate rigidity as observed by Sherrington. The fact, however, that Parkinsonism had set in before the abnormal attitudes of flexion and extension began to appear, and that such attitudes virtually disappeared in dorsal decubitus, impels the authors to regard this condition of hypertonus as part of the Parkinsonian syndrome.

The general question of torsion spasms and their associated attitudes in relation to epidemic encephalitis is pursued further in Chapter XXIX, which is a reprint of an article previously published in 1926 in collaboration with M. A. Thévenard. Here are described the various attitudes of torsion as affecting different parts of the body in patients suffering from post-encephalitis. These are compared with similar manifestations of patients in other circumstances, such as the strange syndrome of abnormal postures and perturbations (torsionsdystonie), at one time considered by M. Mendel as peculiar to members of the Jewish race, and with the attitudes of decerebrate rigidity type sometimes associated with tumours in the thalamo-peduncular region. It is concluded by the authors that some infections, such as epidemic encephalitis, possibly syphilis, and certain intoxications, can produce all the types of dystonic disturbance comprehended in the term "torsion spasms"; but they would displace this term with the more objective one of "attitudes de torsion."

Since 1919, when the disease first began to attract attention, the symptomatology of epidemic encephalitis has always been studied with special care by French observers, and the present series of clinical observations on the post-encephalitis phase, which is enriched with good and helpful illustrations, shows that the subject is still one of absorbing interest in the neurological clinic of the Salpêtrière.

CLINICAL PERIMETRY

By his painstaking and accurate investigations on the pathology of the visual fields, Dr. H. M. TRAQUAIR of Edinburgh has put the whole of English-speaking ophthalmology into his debt; and it is with pleasure that we welcome the appearance of a second edition of his *Introduction to Clinical Perimetry*.[3] The second edition does not depart in any essential feature from the first; the text has been revised and several sections have been rewritten

[1] *Recent Advances in Forensic Medicine*. By Sydney Smith, M.D., M.R.C.P., D.P.H., and John Glaister, jun., M.D., D.Sc., J.P. London: J. and A. Churchill. 1931. (Pp. vi + 194; 66 figures. 12s. 6d. net.)

[2] *Études Neurologiques*. Quatrième Série par Georges Guillain et Th. Alajouanine. Paris: Masson et Cie. 1930. (Pp. 358; 75 figures, 7 plates. 65 fr.)

[3] *An Introduction to Clinical Perimetry*. By H. M. Traquair, M.D., F.R.C.S.Ed. Second edition, revised and enlarged. London: H. Kimpton. 1931. (Pp. viii + 231; 179 figures, 3 plates. 30s. net.)

and amplified, while a considerable number of illustrations have been added.

The average practitioner has little conception of the enormous amount of detailed quantitative and qualitative information which can be extracted from a scientific examination of the visual fields, provided the patient is reasonably intelligent. The science of quantitative perimetry, which was inaugurated by Bjerrum towards the end of the last century, and was introduced into this country by Berry in 1890, is of the first importance in ophthalmological and neurological medicine. In it the determination of the limits of the visual fields is a secondary matter; the essential point is a thorough examination of the visual acuity throughout the whole extent of the field, determining areas of impaired function with quantitative accuracy as well as areas of complete loss of function. In this way the early manifestations of disease are elucidated, and its progress can be followed with accuracy. Further, many pathological conditions, such as the toxic amblyopias, retrobulbar neuritis, and a number of intracranial lesions, which without quantitative perimetry are often a matter for conjecture, can be diagnosed in their earlier stages and followed in their clinical course with extreme certainty. To work out the data upon which this science is based has entailed a great amount of clinical labour; this has been done mainly in Continental clinics, with the one exception of Edinburgh, and Dr. Traquair, who has been entirely responsible for this activity, is to be congratulated on the clarity of the exposition of his views in the present volume, which, although full of detailed information, is fascinating to read. The publishers also deserve congratulations on the excellence of the printing and illustrations.

DR. ERASMUS DARWIN

Most of the essential details of the private life of Erasmus Darwin (1731-1802) may be read in Charles Darwin's short biography of his grandfather. Certain additional unpublished matters of interest are contained in Mr. HESKETH PEARSON'S book *Doctor Darwin*,[4] more especially in connexion with the Lunar Society, which Darwin founded. This was a small coterie of scientists, almost all of them geniuses, including such well-known men as Watt, Priestley, Wedgwood, and Samuel Galton. It took its name from the fact that its meetings were held at the full moon, to enable members to find their way home along the so-called roads of the time, without mishap. It was a society in which every conceivable subject of scientific interest was freely discussed, and there can be no doubt that the discussions served as a stimulus to Darwin's inventive genius. Mr. Pearson has cleverly planned his book so as to make the Lunar Society to some extent the background of his picture, introducing vivid sketches of the principal members and depicting Erasmus Darwin through his friendships. These men foreshadowed the period of immense material progress which has continued uninterruptedly to the present day, and although Darwin is best known as a philosopher and poet, the practical trend of his mind (as became a physician) was always strongly marked.

Mr. Pearson states that there is hardly an invention in the world of to-day that Darwin did not father or foresee. He visualized the submarine, the internal combustion engine, and the aeroplane, conceived the science of eugenics as subsequently worked out by Francis Galton, foresaw that germs would be discovered as the causes of diseases arising in connexion with the exhalations from sewage and burial-grounds, invented a manifold-writer which gave James Watt the idea of his copying machine, planned a canal lock the principle of which was afterwards extensively used, made a shrewd guess concerning the composition of water, which put Watt on the tract of his great discovery, and made many other ingenious inventions. This versatility of his genius has been overshadowed by his famous theory of evolution, the first systematic theory propounded, and the germ of all subsequent developments in that subject. It has been said by Krause that every single work of Charles Darwin may be paralleled by at least a chapter in the works of Erasmus Darwin. He clearly recognized the origin of species through modifications of structure, but he assumed that this modification depended on the inherent impulses of the individual towards the improvement of its natural position, and therefore on the existence of conscious effort. Thus in applying the theory to the vegetable kingdom it became necessary to attribute mental functions to plants, and the weak point in the theory became evident. Mr. Pearson hardly touches on this aspect of Darwin's work; his intention has been to show that the theory of evolution alone gives a very inadequate idea of the scope of Darwin's genius.

It may be mentioned that for general information Mr. Pearson has drawn very largely on the writings of Anna Seward; he is much indebted to her. This lady appears to be the object of a certain amount of quiet merriment on the part of the author, the reason of which is not quite obvious. She cannot be considered to have been other than a good friend to Darwin, and although it is true that she felt a strong affection for him, which was not returned in the slightest degree (the author mentions "amorosities" merely), the humour of the situation is not apparent. Mr. Pearson makes a point of endeavouring to produce a biography that is accurate and at the same time readable; this is in keeping with a modern tendency and is to be commended, but the popular craving to be amused does not deserve to be encouraged in serious biographical work.

PHYSIOLOGICAL CHEMISTRY

The fifth edition of MATHEWS'S *Physiological Chemistry*[5] will no doubt find as warm a welcome as did its predecessors. It is a unique book. Including the index it runs to over 1,200 pages. The section on practical work and methods occupies 281 pages—that is, it is as big as a fair-sized practical textbook. From beginning to end—from the preface to "A word to the student" which introduces the section on practical work—it bears the impress of a vivid personality. The author's enthusiasm shows itself in the turn of phrase which he employs, and, we may add, in the speculations on which he does not hesitate to embark. The book contains an enormous amount of information; the industry of the author has been amazing, and he has succeeded in bringing the text very satisfactorily up to date. It must be considered, perhaps, as a reference book rather than as a textbook; even allowing for the fact that the author's obvious enthusiasm does much to carry his readers with him, it is too detailed to serve any but a heroic student as material for steady reading. Provided, however, that the reader is able and willing to exercise his critical and discriminative powers, it is a mine of useful information and, here and there, of highly suggestive thought. Frankly, however, we feel that at times Professor Mathews carries the privilege of speculation a little too far. Roundly to suggest that memory may have its basis in chemical processes in the fatty acid chains of the lipoids similar to those which occur in the drying oils when exposed to oxygen, or to speak of linseed oil being "taught to oxidize itself," seems hardly justifiable, and there is the risk that some unfortunate student might take such phrases too seriously.

[4] *Doctor Darwin*. By Hesketh Pearson. London and Toronto: J. M. Dent and Sons, Ltd. 1930. (Pp. xi + 242, illustrated. 10s. 6d. net.)

[5] *Physiological Chemistry*. By Albert P. Mathews, Ph.D. Fifth edition. London: Baillière, Tindall and Cox. 1930. (Pp. xviii + 1233; 109 figures. 31s. 6d. net.)

A book with similar aims, but very different in form, is BODANSKY'S *Introduction to Physiological Chemistry*.[6] It is written in a quieter style, which has yet, at times, a certain air of breathlessness. The author ranges widely over the field of biochemistry, and, in his opening chapters, discusses questions such as the laws of thermodynamics, entropy, and free energy, in their bearing on the phenomena of life. He avowedly writes with the idea of presenting current thought and current facts, and is prepared to admit that the picture may very rapidly change. Here he is undoubtedly right. Not merely is finality impossible, but few such books are likely to survive many years before they become obsolete in greater or less degree. The present volume contains a very adequate survey of the known facts. It is suitable for the advanced rather than the elementary student, but it, or something of the sort, might well find its way into English medical schools, where theoretical textbooks of biochemistry are sadly wanting.

NOTES ON BOOKS

The little book on *Simple Beginnings in the Training of Mentally Defective Children*[7] has been reissued as a memorial edition to its author, the late MARGARET MACDOWALL. It is a fitting tribute to one who was recognized as a pioneer in her subject, and who in her day was the best known and most capable practical teacher of defectives in this country. For the work to which Margaret Macdowall devoted her life was characterized not only by a high degree of originality and inexhaustible patience, but also by the most complete sympathy with, and love for, her pupils. The book, however, is something more than a memorial to one who has passed away: it is full of sound common sense and practical advice. After a brief description of various types of defectives, and an account of the general principles of training, it treats in detail of the methods by which even low-grade children may be taught to walk, to speak, to use their hands to practical purpose, to read and write, to sew, and to occupy themselves in various kinds of useful tasks. It is not intended as an educational guide for the special school group; its concern is mainly with defectives of lower grade and younger age; but for the training of these it probably remains the best practical handbook on the subject, and it is certainly one which no teacher of young defectives can afford to be without.

The first number of the new volume of the *Annals of Medical History*[8] opens with Professor G. W. Corner's account of the rise of medicine at Salerno in the twelfth century, which shows that from 1080 onwards medicine there was a combination of the direct, practical attitude of mind of Salerno with the Arabian systematic formalism. Dr. E. D. Baumann of Oosterbeek, Holland, writes on the ancient problem, discussed by Plato, whether fluids taken by the mouth passed into the stomach or into the lungs. A regimen sent in 1315 by Peter Fagarola of Valencia to his two sons, who were students at Toulouse, is translated by Dr. Lynn Thorndike of New York. Contrasting with these in point of time is the account of "Old days" (in the 'nineties of the last century) of an intern at the Chambers Street Hospital, New York, by Dr. J. B. Cutter, now of San Francisco, who graphically sketches the life at this emergency hospital, not far from the "Bowery," and the ambulance calls, on an average ten daily, and its clanging bells. Professor A. S. Warthin's fourth instalment of the physician of the "Dance of Death" is generously illustrated, and, like the previous parts, full of interest. The life-history of C. W. Hufeland (1762–1836), professor of medicine at Boston, whose portrait appears on the cover, is sketched by Dr. I. A. Abt. The frontispiece presents Antonio Vallisneri, who died two hundred years ago, and was professor of medicine at Padua; he was, Dr. J. Franchini tells us, induced to enter the physic line by Malpighi, whose devoted student he became. Thomas Dale of Charlestown, South Carolina, translated into English works originally in Latin by John Freind and Lommius, and being, as Dr. R. E. Geibels shows, a versatile character, was interested in the stage, wrote epilogues as well as prologues, and was an assistant justice of the peace. The Mütter Museum of the College of Physicians of Philadelphia is described by its curator, Dr. H. P. Schenck, and the medical incunabula in the John Crerar library, Chicago, and in the University of Michigan, are duly put on record. An editorial on the Institute of the History of Medicine at the Johns Hopkins University shows that five courses of lectures are being given in this academic year, one of them by the visiting lecturer, Sir D'Arcy Power. Among the book reviews is a very appreciative notice by the editor of Plarr's *Lives of the Fellows of the Royal College of Surgeons of England*.

Contemporary Thought of Germany[9] is a very readable introduction to German philosophy by Dr. TUDOR JONES, who correlates, with much penetrating analysis, the more important contributions to the subject from the time of Kant to Rudolf Eucken. The first part of the volume traces the sources of modern German thought, and gives brief illuminating epitomes of the work of a number of writers (including Lotze) who are associated with the modification or development of the teachings of Kant and Hegel. In his account of the schools of Schopenhauer and Nietzsche the author is liberal enough to mention Richard Wagner, who, he asserts, deserves to be known not only as a musical composer but as a philosopher and poet as well. The return to pre-Kantian philosophy is described in a chapter on phenomenology, which contains an interesting note on Husserl, and the survey concludes with the religious *a priori* school of Eucken and Troeltsch. This volume is to be followed by another dealing with contemporary writers in the various branches of the philosophical sciences and of religion.

PREPARATIONS AND APPLIANCES

ERGODEX

Ergodex is a new preparation issued by British Drug Houses Ltd. It is made from ergot of rye and contains the whole alkaloidal content of this drug. It is standardized biologically to contain 0.03 per cent. of ergotoxine, and the dose is 10 to 30 minims. It is common knowledge that the official liquid extract of ergot is practically inert, and recent investigations have shown that it is difficult to make up a preparation whose activity will not deteriorate on keeping. The makers claim that the activity of ergodex is retained as long as the container is kept corked and protected from bright light.

COLLOIDAL IRON

Idozan is a colloidal iron solution (5 per cent. iron) manufactured by A/S Serpens, Copenhagen, and marketed by Messrs. Coates and Cooper. The special advantages claimed are that it has a pleasant taste, does not discolour the teeth, does not irritate the stomach, and does not produce constipation.

HEXYL-RESORCINOL SOLUTION

"Hexyl-Resorcinol Solution S.T.37" is a solution containing 0.1 per cent. of hexyl-resorcinol in 30 per cent. glycerin and 70 per cent. water, prepared by Messrs. Sharp and Dohme Ltd. The surface tension of this solution is 37 dynes per cm. (s.t. pure water = 77 d. per cm.). The makers claim that this is a stable non-toxic solution that can be applied undiluted to wounds and has an exceptionally powerful and rapid germicidal action. They recommend the solution for open wounds, burns, scalds, and for the hygienic care of the mouth and throat.

DIET AND THE TEETH

A substantial part of Professor Edward Mellanby's interesting Hastings Popular Lecture, of which the full text appears in our *Supplement* this week, was devoted to the relation of food to dental caries and pyorrhoea alveolaris. As the medical members of his audience were well aware, Mrs. Mellanby has for many years conducted researches on the manner in which disease of the teeth in animals and man is influenced by their diet. The results of her work are being published in three parts by the Medical Research Council, which has supported this important investigation. Part I, which came out in 1929 and was noticed in these columns,[1] presented evidence that in dogs the structure of the hard dental tissues is subject to the play of dietetic factors. The essential outcome of these researches was that "if sufficient vitamin D is ingested, perfect teeth are formed; in its absence, imperfect teeth always result." The second part of her work has appeared lately,[2] and deals with a variety of results obtained by animal experiment. The pages of greatest interest to the medical profession are those which deal with the influence of diet on the periodontal tissues and in the development of pyorrhoea alveolaris. Mrs. Mellanby has shown that if young puppies are fed on diets deficient in vitamin A, the periodontal tissues develop abnormally, and the animals are prone to suffer from pyorrhoea alveolaris in later life. Her conclusion is: "A deficiency of vitamin A in the diet leads to hyperplasia of the subgingival epithelium and to its subsequent invasion by pathogenic organisms. A deficiency of vitamin D, on the other hand, results in defects of the alveolar bone." A significant fact in connexion with the experimental work on periodontal disease is the relative importance of an adequate diet during the early period of life, when the teeth and periodontal tissues are developing. "If a puppy's diet has been deficient in vitamins A and D during the early months of life, the dog is liable to develop periodontal disease at a later stage, whatever the subsequent diet. On the other hand, a perfect diet in the developmental period either prevents or greatly inhibits the production of periodontal disease at a later stage, even if the diet is subsequently deficient in vitamins A and D." In the case of hard tissues of the teeth, Mrs. Mellanby showed that the accepted "normal" structure of human teeth was in reality a very defective condition peculiarly liable to disease. Some of the author's remarks in this part of the report suggest that a like difficulty occurs in regard to the periodontal tissues, and that many authors have accepted imperfect conditions as the normal standard in man.

The association proved to exist between vitamin A deficiency and periodontal infection is of great interest and significance. In the first place, it suggests a probable cause for the occurrence of pyorrhoea alveolaris in man; it suggests also the means of prevention—namely, correct feeding in infancy. This is an advance of first-rate importance, because pyorrhoea alveolaris is a very common disorder, and there are few complaints which have been held responsible for so wide a variety of unpleasant sequels. For the details of the evidence in support of these conclusions we must refer our readers to the report itself, in which the essential points are illustrated by a series of admirably clear photomicrographs. It is, however, worthy of remark that some of the carefully controlled feeding experiments on individual animals were continued for no fewer than eight years. Another interesting feature of these experiments is that they reveal a new function of vitamin A. This was the first fat-soluble vitamin to be identified, but the discovery of the separate identity of the fat-soluble calcifying vitamin by Professor Edward Mellanby in 1917 diverted attention from its associate. Subsequent investigation rapidly revealed the remarkable association between vitamin D and ultra-violet light. The interest aroused by the discovery of a means of prevention of rickets led to vitamin A being neglected for many years. The part played by vitamin A as an essential factor in maintaining the resistance of the body to bacterial infection is now being established, and it seems possible that in the end vitamin A will prove to be just as important as vitamin D. A further point brought out clearly by Mrs. Mellanby's work is the great importance of infant feeding in the development of healthy teeth. The normal development of the hard structures of the teeth and jaws depends on an adequate supply of vitamin D, while the normal development of the periodontal tissues is equally dependent on an adequate supply of vitamin A. Moreover, any damage done to the teeth by lack of vitamin during the development stage appears to be more or less permanent, for it can be checked, but cannot be cured, by correct feeding in later life. The equal need for the two vitamins A and D is a matter of great practical moment, for it shows that as far as the teeth are concerned cod-liver oil cannot be replaced by irradiated ergosterol alone, and that both vitamins must be present in a preparation if it is to form an efficient substitute for cod-liver oil, at any rate as regards the development of healthy teeth.

The remainder of this volume gives an account of a variety of researches. Many attempts were made to bring about dental caries in animals, and particularly in dogs. It was found that only with extreme difficulty could caries be produced in dogs which had healthy teeth. For example, when holes were made in the teeth, and these were infected with *Streptococcus*

[1] *British Medical Journal*, February 15th, 1930, p. 292.
[2] Medical Research Council Special Report Series, No. 153. Diet and the Teeth. An Experimental Study. Part II. A, Diet and Dental Disease in Animals other than the Dog. B, Diet and Dental Structure in Mammals other than the Dog. By May Mellanby. London: H.M. Stationery Office. 1930. (2s. 6d. net.)

mutans, caries rarely followed. It is also of interest to note that the addition to the diet of large quantities of fermentable carbohydrates, such as glucose, had no demonstrable action in producing caries. Another subject investigated was the response of the teeth of animals to attrition. The power of the pulp to form secondary dentine is one of the main defensive mechanisms against the destruction of teeth by caries in the human being. Mrs. Mellanby finds that the production of secondary dentine in the teeth of puppies in response to attrition is greatly influenced by the diet. "A diet rich in vitamin D results in the formation of a large amount of well-calcified secondary dentine. A diet deficient in this substance and rich in cereals is associated with either the formation of defectively formed secondary dentine, usually small in amount, or no reaction. The amount and character of the secondary dentine formed is a measure of the resistance of the living tooth; none is formed in a dead tooth." She has investigated also the action of diet on the calcification of the teeth of rabbits and rats, with results confirming those obtained with dogs. The structure of the teeth of rabbits and rats is controlled by vitamin D in the same way as is that of the teeth of dogs. On the other hand, green vegetables, which are rich in vitamin A but contain little vitamin D, have small effect on the calcification of the teeth of rabbits, though they improve the general health. She concludes that: "In view of the differences in the types of teeth of the dog, rabbit, and rat, the results obtained suggest the probability that the tooth structure of all mammalia is controlled, as regards calcification, by the same dietetic and environmental factors as are described in Part I of this report." The third and concluding part of Mrs. Mellanby's report on this series of researches will be concerned with the structure of human teeth and the part played by diet in the resistance they offer to disease.

OUT-PATIENTS

The problem of the out-patient departments of hospitals is a very real one. As at present conducted these departments entail a gross waste of the money of the charitable public and of some other agencies which give them financial support, and a corresponding waste of the time and energy of the medical and other staffs who are engaged in them. This fact is, however, not recognized, or is ignored, by the lay governing bodies of the hospitals concerned, and is tolerated without active disapproval by some members of the medical staffs themselves, so that the abuse has reached very large dimensions. At intervals over a long period of time the British Medical Association has called attention to the matter, and the Council of the Association has now issued a report on the subject, which it asks the Divisions to consider carefully, and which will be submitted for approval in July next to the Representative Body. This report was published in the *Supplement* to our issue of February 21st last.

It would not be easy to set out the matter more clearly than is done in the document to which we call attention. The basic contention is "that the primary object of the out-patient department should be for consultation, and that such departments should undertake only such treatment as cannot in the best interests of the patient be obtained elsewhere." Secondary, but important, objects are to deal with accidents and sudden emergencies in the first instance, and to continue for a short time the necessary oversight of certain limited classes of discharged in-patients. No substantial qualification or addition to these statements is required. It may be admitted that until recently, and in times of severe economic depression, there has been a quite small class of the population—either the dependants of the poorest type of insured persons, or a similar type among those who are not technically "employed," and so do not come within the ambit of the National Insurance scheme—which could not afford to pay private medical fees either direct or through a voluntary contract system, and which therefore depended for medical advice and treatment either upon the Poor Law arrangements or upon charitable provision. It may have been legitimate for such persons to evade the Poor Law by seeking charitable aid, but strictly considered, their number has never been large; and to-day, with a reformed Poor Law administration on the one hand, and with a multiplication of public medical service schemes and of voluntary contractual arrangements on the other, they should have no real difficulty in obtaining ordinary medical attention outside hospitals. Complete provision would, of course, be made for all such persons under a national medical service scheme such as that lately propounded by the British Medical Association, and the last excuse for the provision by hospitals of ordinary medical attendance through their out-patient departments would disappear.

What, then, beyond the considerations we have discussed, are the arguments raised in defence of the waste of out-patient departments as now usually conducted? The Council's report mentions them under three heads. They are all unsubstantial. Clearly, as regards teaching hospitals, with a still abundant choice of cases, and more time for the teacher to devote his attention to each, more effective teaching could be given if there were fewer out-patients. Again, the allegation, not often explicitly stated, but sometimes implicit in the remarks of members of hospital boards, that general practitioners as a class are unable properly to treat such cases as would be excluded from hospitals under the restrictions suggested, is untrue. The average practitioner of to-day has the requisite skill and experience and knowledge, and such help as he needs would be given much more effectively than now in the reformed out-patient department. Further, the desire of hospital boards to make an emotional appeal to the charitable public by advertising the large numbers of out-patient attendances is surely mistaken. We cannot but think that very little propaganda would be needed to persuade the hesitating

benefactor that quality of service is more important than number of attendances.

The work of the almoner, where there is one, is being very carefully and skilfully done at many hospitals, but the check so applied cannot effectively prevent abuse so long as the present policy of hospital boards of management prevails. If this policy were changed, and the suggested restrictions imposed, something more would be required, and that is the full co-operation of the medical profession. This is of the first importance. The medical staff of the out-patient department will have to refrain from giving continued attendance to any patient who can be adequately seen to elsewhere, and to review these cases more frequently and more carefully with this object in mind. It will be necessary, also, for general practitioners to refrain from sending to hospital (except for purely consultative purposes) any case which can be dealt with otherwise, to resist every temptation to shift to others their own responsibility for cases which tend to be obstinate and tiresome, and always to send a brief medical report with such patients as they refer. There are many places where, in present circumstances, no attempt is made, either by hospital staff or general practitioner, to do these things. Under the suggested new conditions we believe that a successful effort could be made by the profession itself to insist upon their performance. It would be the duty of the profession to make such effort.

The Council's report still awaits the observations of the Scottish Committee of the Association with regard to its application to Scotland. There may be a few respects in which some modification will be required there. In the meanwhile, it is interesting to note the arrangements now made in Scotland whereby it is incumbent upon insurance practitioners to compile returns of all insured persons whom they refer to hospitals, together with the reasons for such reference. These arrangements, and the necessary forms, have been settled by agreement between the Association and the Scottish Department of Health, and seem likely to produce interesting and valuable results.

CHRONIC ULCERATIVE COLITIS

Chronic ulcerative colitis can always be relied on to arouse a lively discussion. It is common enough to come within the experience of most medical practitioners, and because of the long-continued course of the disease there is usually opportunity for observing at leisure the effects of medical or surgical treatment. The open-minded listener at the debate on this subject at the Royal Society of Medicine, on March 11th, probably came away with the generalization fixed in his mind that some cases of chronic ulcerative colitis are incurable and others curable. It would be interesting to know whether in the future this open-minded listener will incline to treat his cases of chronic ulcerative colitis by appendicostomy, antidysenteric serum, lavage, ionization, serum, vaccine, psychology, or starvation.

The discussion was opened by Dr. Arthur Hurst, who dealt chiefly with the medical aspects of the disease. Dr. Hurst considers that ulcerative colitis is allied to bacillary dysentery, and that many cases can be cured by antidysenteric serum. During the ten years or so which have elapsed since Dr. Hurst first advanced this theory there has been plenty of opportunity of observing how it worked out in practice, and it seemed to be the general impression of those who took part in last week's discussion that although a few cases of ulcerative colitis might be due to bacillary dysentery and curable by antidysenteric serum the great majority of cases must have a different pathology. Subsequent speakers pointed out that laboratory tests, both bacteriological and serological, were almost invariably negative for bacillary and amoebic dysentery. Dr. Bargen's theory that chronic ulcerative colitis is a streptococcal infection of the wall of the intestine was also criticized as an explanation of the disease, but there is no doubt that various types of faecal streptococci are to be found in the ulcers. It is, however, more reasonable and in accordance with the observed facts to regard these bacteria as secondary invaders, proliferating in tissue damaged by some antecedent agent. Vaccines and serums have often been regarded as useful in the treatment of chronic ulcerative colitis, but such treatment is most likely to be successful when the vaccine is made from the bacteria which have been isolated from scrapings from the ulcer. The agglutination test may be used for determining which of the colonies of bacteria should be used for the preparation of the vaccine.

The surgical side of the question was put forward by Mr. Lockhart-Mummery, who advocated appendicostomy as the most satisfactory treatment in the great majority of cases. This relegation of the disease to the surgeon was challenged by several subsequent speakers, who claimed equally good results from colonic lavage, ionization, and simple dietetic treatment. In fact, one contributor to the discussion claimed to have had a closer acquaintance with the disease than any who had spoken hitherto, because he had himself suffered from it as a student; and he seemed to imply that he attributed his recovery to the fact that he had not received any of the different forms of treatment advocated by the previous speakers. One point in practical procedure received a good deal of attention —namely, whether or not it is necessary to use the sigmoidoscope for the diagnosis and observation of the course of the disease. Dr. Letheby Tidy regards the sigmoidoscope as unnecessary, or even harmful, and he gave descriptions of cases diagnosed and treated without its use. Most of the other speakers, physicians as well as surgeons, dissented from this view, and the president of the Section, Mr. Lionel Norbury, gave several instances in which the diagnosis as between ulcerative colitis and carcinoma was only possible by sigmoidoscopic examination.

In spite of so many different expressions of opinion by those who took part in this discussion the listener

would probably have recognized agreement on several important points, such as the following. That chronic ulcerative colitis is a disease which requires a very thorough bacteriological and radiological investigation; that the disease runs a long course and often relapses; that whatever medical or surgical treatment is undertaken must be selected according to the requirements of the individual case, and continued with perseverance by both patient and doctor.

INQUIRY INTO THE INCIDENCE OF CANCER AND ITS HISTORY AFTER TREATMENT

This collective inquiry, which is of great importance, not only to the medical profession of this and other countries, but also to the peoples of the entire world, was launched by the British Medical Association in 1929. As originally planned, it requested medical practitioners to make returns, on the questionary supplied to them, of all cases of cancer of the breast, cervix, rectum, and tongue that came under their notice from October, 1929, to September, 1930; it was added, however, that the scope of the inquiry was not to be limited to new cases, but should include any patients still alive at the commencement of the period under review. The reports of 2,250 cases have now been received, and it is quite conceivable that the limitation of the time from October, 1929, to September, 1930, may have misled many practitioners. As 2,250 cases are altogether insufficient for the purposes of this inquiry, an urgent appeal is made by the Honorary Director of Collective Scientific Researches for a large number of further returns. These need not be limited to the period from October, 1929, to September, 1930, but should include all patients suffering from, or who have suffered from, cancer, and of whom the practitioner has recent knowledge. It is especially desired that all patients with cancer of the breast who, to the knowledge of the practitioner, have survived for a period of five years and upwards from the date of operation, should be returned. A very widespread response to this appeal is hoped for. All practising medical men and women have it in their power to contribute to an investigation whose outcome may have far-reaching consequences. Forms of the questionary can be obtained on application to the Medical Secretary, British Medical Association House, Tavistock Square, W.C.1.

THE SERVICE REPORTS

Our attention has been drawn to an error in the *Journal* of February 21st (p. 323), under the heading "Health of the Army, Report for the Year 1929," where there appeared the statement that "the average duration of treatment of each case of gonorrhoea is approximately three months." This should have read "approximately two months." The mistake was repeated in an annotation on the Service Reports in our issue of March 7th (p. 409) in the sentence: "It will be noted in the reviews we have published that the naval medical authorities record an average of nineteen days for the treatment of gonorrhoea, while in the Army the period of treatment for the same disease is approximately three months." We apologize for the error and take this opportunity of correcting it. It was not intended to magnify the period spent in hospital, nor to suggest that conditions are alike in the two Services; but rather to draw attention to the fact that, whereas in the Army the average number of days under treatment for all cases of gonorrhoea was stated to be 58.8 in 1929, in the Navy the average duration of treatment for all cases of gonococcal infection and sequelae was 19.6 days. Circumstances differ ashore and afloat, but the personnel of the fighting Services are a selected population, who are either fit or unfit for duty. Sickness causes days off duty and expense to the State in the Army as in the Navy. If, therefore, it is possible for one Service to reduce the time taken in returning men to duty, and so to effect economy, the methods by which this is achieved are worthy of discussion and investigation, in the hope that they may be applicable to all three Services. Our real plea was for a combined statistical report, so that attention could readily be focused on outstanding points, the discussion of which would lead to mutual benefit.

TYPHUS RESEARCH IN MALAYA

The annual report for 1929 of the Institute for Medical Research, Kuala Lumpur, in the Federated Malay States, contains a particularly interesting account of a concerted investigation on the local problem of tropical typhus. Dr. L. Anigstein of Warsaw was appointed as a research student in this connexion; he introduced some new methods of technique, and by collaboration with various departments of the Institute, considerable progress was made in clearing up some previously obscure questions. It is concluded that there are no obvious clinical features on which a differential diagnosis between the two serologically differing forms of tropical typhus can be based; agglutination tests are therefore always essential. Careful search was made for an initial lesion, but none was found in this disease. Some of the delirious or stuporous patients manifested the curiously slight degree of pyrexia that has been observed in European typhus; in two tropical cases, which ended fatally, the average temperature during the last four or five days remained under 100° F. An eye sign of diagnostic value was noted in 40 per cent. of the cases; there was a characteristically mild suffusion and the eyes were half closed, somewhat watery, and faintly glistening, giving a dull yet anxious appearance to the face. Injection of the vessels was usually not marked, much less so than in cases of leptospirosis. Complications were frequent, the commonest being acute bronchitis or broncho-pneumonia early in the second week. In two instances thrombosis of the veins of the leg occurred, and other complications mentioned in the report are bilateral parotitis, unilateral facial paralysis, and subdural haemorrhage. The virulence of this disease appears to be increasing, the percentage of fatal cases having risen from 4 in 1927 to 14.7 in 1929. Experimental work was conducted on guinea-pigs, rats, and rabbits, the human strains of the virus showing low virulence for guinea-pigs when inoculated intraperitoneally, though a marked decline of body weight, followed by death, occurred when the animals were inoculated intrascrotally. Complete immunity was afforded for at least two and a half years by one attack of the disease. Some evidence was obtained that rats might act as a reservoir for the virus of tropical typhus.

Special attention was paid to the possibility of infection through lice, but the evidence was inconclusive. This issue of the report of the Institute also contains accounts of malaria, mosquito, and leprosy investigations.

INTERNATIONAL FELLOWSHIPS FOR RESEARCH

The International Federation of University Women has made a definite contribution to the advancement of knowledge and the promotion of friendly international relations by bringing together in a convenient and inexpensive form particulars of a surprisingly large number of travelling fellowships and scholarships available to graduate students and research workers of most nationalities and both sexes.[1] The individual worker may be aware of the funds available for the endowment of research in his special subject by graduates of his own university. He is less likely to be familiar with the resources of the numerous funds not so restricted, and such knowledge may well be of vital importance to him at a critical point in his career. The list of international fellowships contains concise but sufficient information, clearly tabulated in two sections. The first of these indicates the travelling fellowships available to workers from a particular country; the second, fellowships not restricted as to the country of the holder. The United States of America do not appear in Section I, because information as to these is available in a list published by the Institute of International Education, to which graduates in the United States would naturally refer. The list is preceded by a review of the existing endowment of research and a cogent plea for its extension, particularly in the direction of an increase of international fellowships. The medical reader will appreciate the illustration drawn from the record of the first fifty holders of the Beit Fellowships. Apart from the general cultural value of a period of travel or residence abroad, the progress of specialization in particular countries and particular institutions (a marked feature of modern development) is making facilities for foreign travel increasingly important to the pursuit of given lines of research. British university women have played a leading part in giving the establishment of international fellowships a prominent place in the programme of the International Federation, and the Federation has done good work both in promoting an endowment fund and in calling public attention to the claims of this form of benefaction.

THE PROBLEM OF RACE

The latest volume in the well-known "To-day and To-morrow" Series is an essay by Sir Arthur Keith entitled, *Ethnos, or the Problem of Race*.[2] The author claims to have considered the problem from a new point of view, and this claim may be admitted. In very short compass he brings a knowledge gained from the study of prehistoric man to bear upon the racial problems of to-day, looks at the whole matter from a purely evolutionary standpoint, and in the end gives a short answer to the questions which he asks: "Would it be best for each race to protect and strengthen the heritage nature has bestowed on it? or Would it be best to obliterate racial boundaries by universal intermarriage?" A large proportion of the essay has reference to the work of Thomas Henry Huxley and his articles and lectures on "Man's Place in Nature." Incidentally, Sir Arthur Keith remarks: "From long experience I have learned that it is dangerous to disagree with any of Huxley's verdicts. He was nearly always right; very few of his judgements have been reversed." But evidence as to the discrimination of human races has accumulated since Huxley's day. Sir Arthur recognizes that human races are differentiated, not merely by physical, but also by psychical characteristics; and that the evolutionary process, essentially aided by segregation owing to physical geographical features, has gone a long way towards establishing a considerable number of definite races of mankind. He holds that this natural evolutionary process has been interrupted by the relatively recent conceptions of "nationality" and the desire for "self-determination," that these new conditions were initiated when man entered on his agricultural or economic stage, and that they constitute a new and substituted attempt to evolve real fresh races. "When races meet and mingle in strange lands, or when they are thrown together by economic necessity, Nature's efforts at race production are thwarted thereby, but she at once sets to work to repair the mischief and to build up by fusion a new race. Nation-building is the first step in race-building." This is a most interesting theory, which no one in this century will be able to verify, but our generation is very vitally concerned with finding the best way to solve the difficulties of the present stage of civilization and to preserve the peace of the world. As Sir Arthur Keith concludes, "Evolution of man is a theory which must be constantly applied in the affairs of every-day life."

THE TEACHING OF HELMINTHOLOGY

Some years ago, as our readers may remember, Professor R. T. Leiper protested against the inadequate and often erroneous treatment of the parasitic helminths in medical textbooks. A similar protest has recently been made by Dr. N. A. Cobb, one of the leading exponents of nematodes (or "nemas," as he prefers to call them) in the United States.[1] Dr. Cobb, however, is concerned with the misstatements and omissions in zoological textbooks, and with free-living as well as parasitic forms. He has examined sixty recent editions of well-known textbooks, and finds that not only is the treatment of this phylum antiquated and inadequate (about three times as much space being devoted to the echinoderms as to the nematodes), but is full of errors, both of omission and commission, sometimes to the extent of ten on a page. In the few textbooks with no misstatements of fact, the group is almost wholly ignored. These errors he classifies and analyses. Among the more striking are: failure to state that nematodes moult, and to note the absence of cilia and of striated muscular tissue, acceptance of ascaris as a typical nematode,

[1] *A Guide and other Information Fellowships for Research*. Obtainable of the Secretary, International Federation of University Women, Crosby Hall, Chelsea, London, S.W.3. (1s. 3d. post free, or 9d. to members of the Federation.)

[2] *Ethnos, or the Problem of Race Considered from a New Point of View*. By Sir Arthur Keith, F.R.S. London: Kegan Paul, Trench, Trubner and Co., Ltd. 1931. (2s. 6d. net.)

[1] *Science*, January 9th, 1931, p. 22.

inclusion of members of other phyla in this group, and omission of all mention of free-living forms, and of forms parasitic on plants. Dr. Cobb is an enthusiast, and perhaps attaches excessive importance to the phylum in a general zoological course. But much of his complaint has substance. Our students are brought up with the idea that ascaris is a typical nematode—just as they are taught that *Fasciola hepatica* is a typical trematode. These beliefs are far from being correct. Both creatures are among the most atypical of the groups they are supposed to represent, and their study in elementary classes gives rise to many of the prevailing misconceptions in parasitology. The only reasons for their retention as examples are tradition and the ease with which specimens may be procured. It is doubtful if either of these reasons is valid. We no longer teach that spontaneous generation of parasites occurs; and with very little effort other common nematodes and flukes could be obtained. Those who frame a course in general zoology for medical students—the class with which we are concerned—are influenced by two distinct sets of circumstances. First, they must provide a general survey of the animal kingdom which will prepare the student for his more detailed study of the highest mammal. In the second place, those forms must be studied which are of direct interest to the medical man as causes of disease. There is very much to be said for the inclusion of a course in animal parasites at a stage when the student is able to appreciate their real significance—that is, when he studies the plant parasites or bacteria and their reactions. At the present day, unfortunately, this part of his training is included with his general zoology course, or else it is ignored. Very few medical men have even an approximate idea of the losses caused to the world at large by the nematodes. About a third of the inhabitants of the world harbour one or more species. An even larger number of domesticated animals do likewise—the loss in the United States alone from this cause amounts to over 100 million dollars yearly. Many plants are infected with nematodes; and when one considers that at least half the known species are free-living, the importance of the group becomes evident. From both points of view, therefore, it is necessary that the medical student should possess an accurate, if elementary, knowledge of the phylum, and Dr. Cobb has good reason for his complaint that our teaching is, in general, not only inadequate, but inaccurate.

Among the candidates recommended by the Council of the Royal Society for election as Fellows are: Alfred Joseph Clark, M.D., F.R.C.P., Professor of Pharmacology, University of Edinburgh; Charles Stanley Gibson, M.Sc., Professor of Chemistry, University of London (Guy's Hospital); Charles Robert Harington, Ph.D., Reader in Pathological Chemistry, University of London (University College Hospital Medical School); Sir Alexander Cruikshank Houston, M.B., C.M., Director of Water Examinations to the Metropolitan Water Board; Sydney Price James, M.D., Lieutenant-Colonel I.M.S., Adviser on Tropical Diseases to the Ministry of Health; and Wilfred Trotter, M.S., F.R.C.S., Surgeon to University College Hospital.

THE HASTINGS LECTURE

PROFESSOR MELLANBY ON "DIET AND HEALTH"

The fourth popular lecture of the series established by the British Medical Association to commemorate the life and work of Sir Charles Hastings, its founder, was delivered in the Great Hall of the Association's House, Tavistock Square, London, on the evening of March 13th, by Professor EDWARD MELLANBY, M.D., F.R.S. There was a large audience, and the hall was almost filled. The full text of the lecture, which was illustrated throughout by lantern slides, appears in the *Supplement* to the present issue.

LORD MOYNIHAN'S INTRODUCTORY SPEECH

The chair was taken by LORD MOYNIHAN, President of the Royal College of Surgeons of England, who, in introducing the lecturer, spoke as follows:

"I regard it not only as a very great pleasure but as a very high privilege to be asked to take the chair to-night for my friend Professor Mellanby, and if I could arrogate for a moment to myself a wider authority than I possess in my person, and speak on behalf of the whole medical profession, I should like to say that we owe an immense debt of gratitude to Professor Mellanby for the work that he has done, not only in the laboratories, but in the wards. I understand that the majority of the audience to-night are lay people, and they may be interested to hear that in listening to Professor Mellanby they have before them a man who has conquered the age-long problem of rickets. Rickets, as you know, is a disease which in the large cities of this and other countries has been endemic for generations, and you may still see in the maimed and twisted and warped limbs and bodies of men going about the streets those who in their infancy and childhood suffered from this disease.

"Some time ago, to my great happiness, Professor Mellanby became interested in the problem of cancer, and his researches into the metabolism of the cancer cell are certainly able to rank with any other researches which have been carried out in the world, and they will, I hope, in the end be fruitful of good results so far as clinical medicine is concerned. But I should like also to draw attention to the fact that Professor Mellanby's position realizes an ideal that many of us have in connexion with the future progress of medicine. He is the one supremely competent laboratory worker of this country who is also in charge of beds in a great teaching hospital, and in his own person he exemplifies better than anybody in this country the joint work of the research laboratory and the clinical work which is carried on in the hospital wards. I say that he realizes the ideal because everybody who is familiar with the problem and has thought much about it must understand this, that the future progress of medicine is inseparably bound up with the work to be conducted in the laboratories. If I may speak of my own branch of the profession, that of surgery, I would say that surgery as a craft—I have repeated this many times, and it has been as frequently denied, but it is nevertheless indisputably true—has almost reached its limits. It is almost impossible in the future to expect that any organ of the body which has not been attacked will ever be attacked, and it is almost impossible to expect that a greater degree of success will follow upon surgical operations than is now realized in the hands of the great masters throughout the world. So far as surgery is concerned, I think we

may say that Lister's work is now almost fully accomplished, except in this regard, that in giving us safe surgery Lister has given us the strong weapon of research, not only upon men, but upon animals. I feel, therefore, that Lister's work in respect of surgery has been realized almost to the full upon man, and is now the safe weapon for research into the diseases of man and the physiological changes which are brought about deliberately in animals. It is with a special sense of gratification that I want to introduce to you to-night the man who throughout the world in my judgement best realizes what is to be the idea of medicine in the future, one who is a great laboratory worker and a highly competent physician. Professor Mellanby is called a professor of pharmacology, but he ought to be called—and is indeed—a great pioneer in experimental medicine."

QUESTIONS FROM THE AUDIENCE

At the close of the lecture a number of questions were handed up to Professor Mellanby, which he answered. The first question related to the cost of carotene. The lecturer said that carotene was much costlier to produce than irradiated ergosterol. The market price of carotene was some £3 a gram, but as only two milligrams were wanted a day it did not work out very expensively. He added that as much vitamin A as was necessary could be obtained out of ordinary foods, but not, as a rule, sufficient vitamin D. To obtain this vitamin it was usually necessary to go out of one's way—for example, to take cod-liver oil. There was not sufficient vitamin D in ordinary natural food to produce and replace perfect teeth and bones. Vitamin A was abundant in all kinds of liver, and carotene was obtained in carrots and also in green vegetables. There was no reason why anyone should be short of vitamin A when eating natural foods.

Asked whether meat, which he had not mentioned in his lecture, was an important article of diet, the lecturer replied that he did not know. It was important to some people, and not to others. Meat had certain good properties. It had protein of high biological value, it was pleasant to eat, and it had a high specific dynamic value. Fat meat, if it could be eaten, was especially valuable as supplying fat-soluble vitamin. But one could do quite well without meat so long as other articles of food such as milk were taken.

Another question was whether cream contained the same vitamins as cod-liver oil. Professor Mellanby replied that it did, but to a very much less extent. Cod-liver oil was infinitely better and cheaper than cream, but the latter contained some vitamin A, and not very much vitamin D.

Asked as to the effect of the boiling of milk and the cooking of food from the point of view of their natural properties, Professor Mellanby said that all these questions required a lecture in themselves. Put in a general way, the vitamins of milk were not affected by boiling, with the exception of vitamin C, and there was only a small amount of vitamin C in milk in any case. That little, however, would be destroyed to some extent. It was not really a very important point so far as vitamins were concerned whether milk was boiled or not. As to ordinary cooking, vitamins A, B, and D were resistant to the cooking process, though not absolutely so, but vitamin C disappeared very quickly.

Asked whether dental caries in the adult could be rectified by suitable diet, he replied that it probably could, but it was difficult to prove, because adults as a rule were not willing to subject themselves to the kind of dieting necessary. A further question sent up was as to the chemical substances to which vitamins A and D were related. The lecturer replied that vitamin D was obviously related to ergosterol, but what chemical change was caused by the irradiation of ergosterol was not known. Nor was it known what was the chemical relation of vitamin A, but probably it was closely related to carotene. Carotene was a substance containing only carbon and hydrogen; it was an instance of a hydrocarbon, although, of course, a complicated substance. Asked how a dietetic remedy could be applied to the treatment of calcium deficiency, and whether this could have any effect upon chilblains, the lecturer replied that the obvious remedy for calcium deficiency was to give cod-liver oil and milk. The question of the relation of chilblains to calcium deficiency, however, was very problematical. He understood from his clinical friends that the giving of calcium to people suffering from chilblains did not do much good. He was asked whether vitaminized margarine was as good as butter, and replied that some of the margarines which he had tried had been good from the point of view of vitamins; they were certainly much cheaper than butter, though not as palatable. From the point of view of vitamins, most of these English margarines were very accurately made up, and might be said in that respect to be as good as butter.

The final question from the audience was as to whether in the dietary of children dripping was superior to vegetable oils, to which Professor Mellanby replied, "Certainly."

VOTES OF THANKS

Dr. H. B. BRACKENBURY (Chairman of Council), in moving a vote of thanks to the Hastings lecturer, said: "Both the chairman and Professor Mellanby have drawn a very important distinction between observation and experiment, and I think one of the values of a lecture such as this to the public is that that distinction can be made quite clear. Correct observation, even uncontrolled by experiment, is, of course, very valuable, but it is liable to hosts of fallacies. When it is controlled by experiment in a truly scientific way fallacies are detected and eliminated. One of the great values of a lecture of this kind is that it has been given, not only by a practical physician, as Lord Moynihan has said, but by one who is accustomed to eliminate fallacies by experiment. The difference between following a lecture of this kind and reading public announcements which are made either by way of advertisements or newspaper articles by certain persons, sometimes eminent or notorious, is that to-night we have been listening to facts which have been established and observations which have been controlled. Alongside the investigations about which Professor Mellanby has been telling us, there have been some investigations among London school children and others in an entirely different field—namely, the field of discovering the extent of their logical faculties, and, indeed, the logical ability of the average Englishman. It is not generally known, perhaps, that by the age of 7 the ordinary logical faculties of children are very fully developed. It is only their lack of experience which makes them appear guilty of mistakes, and we all of us have experienced the ruthless logic of the small child. It appears, however, that it is not until the child gets to 12 or 14 years of age that in the normal development of the mind it becomes possible for him to detect absurdities and fallacies of reasoning, and we are told that most people never get beyond the stage of general intelligence of a child of, say, 13 or 14 years of age, although, of course, their mental experience is widening. One of the test questions which have been put to children in order to discover their faculty of detecting a fallacy or an absurdity in logic is the following: 'Captain Cook went on three voyages. In the course of one of them he died. Which was it?' It is found that most children of 11 or 12 years of age are unable to answer that question—that is to say,

they are perfectly capable of using a logical argument, but they have very little faculty of detecting an absurdity or a fallacy in an argument. I cannot help thinking that that is the condition of the great majority of the English people, because the statements which are made in certain advertisements, and in certain articles on this subject of diet and health, or diet and disease, are so full of obvious fallacies to those who know, and yet they appear to be entirely accepted by those who follow the advice given in the advertisement or article in question. My point is that we ought to be very grateful for the work of men like Professor Mellanby, and also for his service in coming and expounding these subjects to those of us who know less about them."

Dr. C. O. HAWTHORNE (Chairman of the Representative Body), in seconding the vote of thanks, said: "It will be agreed by all of us that we have had a very full and interesting programme this evening—even a more full and interesting programme than we might naturally have expected when we entered this hall. Lord Moynihan, in introducing the subject, affirmed a proposition which necessarily must have been of interest to all of us. With his great authority he gave us a brief glance at the surgery of to-morrow, and those of us who have escaped so far would hear with much relief that the surgeon in the future is not likely to be more enterprising than he has been in the past. But his second thesis, to which the lecture has been an illustration, was that progress in the knowledge of disease and in the cure and prevention of disease, depends upon a combination of the worker in the laboratory, using chemical and biological tests, with the student of the patient at the bedside—in other words, the clinical physician or practical doctor. As we listened to the story which was unfolded to us so lucidly by Professor Mellanby, I fancy it must have occurred to some of us to wonder how it is that we are here at all to-day. For man has lived upon the surface of this globe for perhaps many millions of years, and not until recently has he had the benefit of expositions from physiologists, and pharmacologists, and experimental laboratory workers. Yet he has managed somehow or other to find out the fruits of the earth and to flourish with a fair amount of satisfaction. I presume that my colleagues are arrayed upon this platform for the purpose of illustrating the effective degree of health which can be obtained under normal conditions at the present day, and I should make a similar application to the members of the audience. Through these long centuries, with so many opportunities to go astray, to eat and to drink the wrong things, man has managed to establish himself, to be fruitful and to replenish the earth, and he has not only done that, but he has done it in all parts of the earth. As Professor Mellanby pointed out to us, somehow or other, without scientific direction, by the accumulation of experience through generations, and by the exercise of that special virtue which we call common sense, man has learned fairly well to nourish himself, and to get suitable food whether on 'Greenland's icy mountains' or 'India's coral strand.' Therefore, while we listen to these new developments with great interest, we shall not come to the conclusion that we have all been absolutely ignorant hitherto, and that it is only by a sort of blundering good fortune that we have managed to exist at all. Nevertheless—and you will notice the difference—roughly speaking, we have taken it for granted that caries of the teeth, rickets, and tubercular and other infections are things more or less inevitable to the human race, that we must take our chance of them, so to speak. But now comes this new knowledge, learned by experiment and by laboratory observation, to fill in these gaps, as we have had it presented to us to-night. The moral that seems to follow from the whole of the story is not only, as Lord Moynihan has told us, that progress in the direction of the cure and prevention of disease depends upon the combination of the clinical and laboratory worker, but the story surely impresses upon us this general conclusion, that the object of medicine in guiding, not only patients, but the public, is the achievement of health, not merely the cure of disease."

Lord MOYNIHAN, in putting the vote of thanks, asked the audience to include Mrs. Mellanby with Professor Mellanby.

The vote of thanks was enthusiastically accorded, as was a further vote of thanks to the chairman, proposed by Mr. BISHOP HARMAN, and seconded by Mr. KIRKLAND, chairman of the Public Health Committee of Wandsworth.

New Zealand

[FROM OUR CORRESPONDENT]

Effects of the Earthquake

New Zealand is an elevated portion of a submarine plateau which extends for about two hundred miles to the east of North Island, and whose precipitous edge is probably the scarp of a great fracture belt. The most active seismic region is at or near the southern end of this scarp. Many great faults and fault zones have been traced for long distances in New Zealand, but only a few have been active since Europeans have occupied the country.

Accumulated earth stresses along the fracture zone in Hawkes Bay or under the sea to the east culminated without warning in an upheaval in the Hawkes Bay Province greater than any recorded in the history of New Zealand. Two important towns, Napier on the coast and Hastings a few miles inland, were struck as by a thunderbolt in the middle of the forenoon on a bright summer day, on January 3rd. Napier, with its mild climate, is a pretty and prosperous seaside resort, of about 20,000 inhabitants; Hastings is smaller, but is the centre of a wide farming district.

The first shake was so severe that standing was difficult or impossible. In the space of a few minutes almost all the brick buildings were dashed to the ground, and the business streets were turned into heaps of rubble. Many motor cars standing in the streets were buried, wooden dwellings lost their chimneys, and the furniture was thrown about and shattered. The water-pipes and sewers were broken, the land on the sea front was raised several feet, and a great mass of earth from the bluff hill behind the town fell towards the sea, sending up great clouds of dust. The ships in the roadstead were forced to turn seaward into deeper water. In this sudden and dreadful situation, many people were dazed, some calling for help, some moaning in pain, some making for safer ground, and all, when they could collect their thoughts, agitated for the safety of their relations and friends. A succession of slighter convulsions shook the ground, and almost immediately great fires added to the terror of the scene. H.M.S. *Veronica*, a sloop which was lying in the basin of the inner harbour, sent out by wireless a brief account of the devastation and an appeal for doctors and nurses. At Wellington, barely two hundred miles away, there had been a slight shock but no damage, and there the sharp call of distress from the *Veronica* fell on astonished ears.

Sailors from the *Veronica* first reached the scene and formed rescue parties. As the railway and bridges were damaged, aeroplanes, ships, and motor cars were dispatched from Wellington, Auckland, and smaller towns, doctors and nurses leaving for Napier and Hastings within

a few hours of receiving the call. The public hospital in Napier and the private nursing homes were found in ruins. The Nurses' Home at the public hospital collapsed like a pack of cards and killed nearly all the night nurses asleep in the building; yet the nurses in the wards, with the masonry crashing about their ears, carried their patients to the open air. Fortunately many of the schools were empty on account of the summer holidays, but at the Technical School many casualties occurred. So far, the death roll at Hastings is 150, and at Napier over 200, but many bodies were buried under the debris, and it will be a long time before the total death roll is known. Fortunately Hastings escaped fire and retained a sufficient water supply.

The St. John Ambulance Association, the Red Cross Society, the Automobile Association, and other philanthropic bodies all rendered every assistance, and in Napier, within twenty-four hours, order was being established out of chaos. An emergency hospital, consisting of a double row of tents extending for about 100 yards, was established on the racecourse. The rescuers, the doctors, and the nurses worked for long hours under the most distressing conditions. At one place groaning was heard from a wrecked building, and when an entrance had been forced through the roof it was discovered that a woman was pinned in the wreckage by her leg. At considerable risk one of the doctors then went down and amputated the limb at the knee-joint so that she could be lifted out. A young doctor at Hastings was told that his own little daughter was buried alive in the ruins, but he continued his surgical work at his dressing station. Napier lay like a town that had been heavily bombarded in the great war. It is impossible to describe the destruction or to do justice to the heroism displayed. As General Napier wrote of the assault on Badajos: "Many and signal were the other examples of unbounded devotion, some known, some that will never be known; for in such a tumult much passed unobserved, and often the observers fell themselves ere they could bear testimony to what they saw."

Now, four days after the calamity, the railroad is open and the roads and bridges are being repaired. The severe cases have been evacuated and at Napier a camp hospital is established to deal with the injured, and with a possible epidemic. This hospital is lit with electric light, has *x*-ray equipment, and all research facilities. The tents and beds are military stores from Trentham Camp, showing that military and naval organization is useful in the dangers of peace as well as in those of war. The inhabitants of the devastated area are nearly all ruined, and a great sum of money will be necessary to relieve the distress and to rebuild homes and shops.

With regard to the aspect of this calamity which concerns our profession, our work is not unworthy of our great traditions. The Minister of Health said: "I should like to express (through the press) most grateful thanks to the medical and nursing staffs. From Auckland to Wellington the response has been magnificent, and has enabled eminent help to be given to all in need of it. The work of the allied services has been no less magnificent."

The annual conference of the New Zealand Branch of the British Medical Association was to have been held at Gisborne at the end of January, but the conference has been abandoned because access to Gisborne from the south for several weeks will be interrupted through the earthquake zone. The bridge over the wide Wairon River between Napier and Gisborne has been almost completely destroyed, and there are many slips on the roads.

England and Wales

Maternal Mortality

In a Chadwick Public Lecture on maternal mortality, delivered in the B.M.A. House on March 11th, Dame Louise McIlroy emphasized the importance of looking upon this problem from a very wide point of view. Discussion about the skill and attention of doctors and nurses in attendance on particular cases was a matter for the medical profession and training centres. The public health authorities and the public must look upon the subject from a national aspect. It involves the organization of more efficient training for doctors and midwives and the establishment of a large number of maternity beds throughout the country. The local health authorities should organize their present hospitals to accommodate a larger number of maternity beds, according to the needs of their districts, and they must have the services of trained specialists. Since many of these institutions were quite unsuitable for adaptation into modern maternity departments, it would be necessary to build new and up-to-date maternity hospitals in the areas where they were most required. The interim report of the Departmental Committee on Maternal Mortality said that hitherto the training of medical students had been most inadequate, and it outlined a scheme whereby this training could be made so efficient that the future general practitioner would have a wide knowledge of obstetrical practice. In order to carry out these recommendations, more maternity beds must be provided. Outside the teaching centres, the main bulk of the midwifery of the country must be in the hands of the family doctor. Dame Louise McIlroy stressed the advantages of ante-natal examinations in the prevention of maternal death, and also the advantage of post-natal care in order to avoid chronic invalidism among women. The movement to give women the benefit of sedatives and anaesthetics was also a controlling factor in the reduction of maternal mortality, because shock was prevented to a great extent and the necessity for operation diminished. Operative intervention always raised the incidence of puerperal sepsis, which accounted for over one-third of the maternal deaths. Whatever scheme was put forward for an efficient national maternity service its chief aim must be that the woman in childbirth must receive the whole attention of the doctor in charge.

Central London Ophthalmic Hospital: Opening of New Wing

A new wing at the Central London Ophthalmic Hospital was opened by the Princess Marie Louise on March 5th. The wing, which consists of four stories, provides, at fees of from six to eight guineas a week, additional beds for private patients, and rooms for the nursing staff. The chairman of the board of governors (Mr. C. M. Wilkins), in describing the building scheme, said that the work had cost £24,000, of which the public had generously provided £20,000 during the past two years. Mr. M. S. Mayou, senior surgeon to the hospital, gave some account of the history of the institution. The hospital was founded in 1843 in the street off Russell Square by Mr. Haynes Walton, surgeon at St. Bartholomew's, and Mr. Alfred Smee, surgeon to the Bank of England and inventor of Smee's telescope. A few years later it was removed to a house in Calthorpe Street, Gray's Inn Road, and a second house was added later. The main building in Judd Street was begun in 1911, and to this centre thousands of patients had come every year from all parts of Great Britain. Mr. Mayou went

on to speak of the value of the hospital in the training of ophthalmologists. Nearly 70 per cent. of the leading ophthalmologists of London had worked in the hospital at some time, and during the past twenty years a large amount of original work on the pathology of the eye had been done there. The new wing would meet the demand which had arisen for the accommodation of patients able to contribute towards their treatment and maintenance, though not able to afford expensive nursing home and consulting fees. A scheme had also been instituted whereby patients whose incomes came within a certain limit could obtain private consultations for a moderate fee. Mr. Mayou believed that such clinics would prove an important factor in the future history of voluntary hospitals, which would have to look for support not only from donations but also from patients' payments. One feature of the new wing, of which Mr. Guy Aylwin is the architect, is the provision of sun balconies attached to a number of the private rooms.

Central Midwives Board

At the meeting of the Central Midwives Board for England and Wales held on March 5th, the following appointments and re-elections to the Board were announced:—The Ministry of Health: Miss Edith Greaves, Miss Ada Davies, Dr. William Allen Daley, and Mr. A. B. Maclachlan. Incorporated Midwives Institute: Dr. John Shields Fairbairn, Miss Anna Albertina Isabella Pollard, and Miss Edith May Doubleday. Royal College of Surgeons of England: Mr. Victor Bonney. Society of Medical Officers of Health: Dr. J. J. Buchan, M.O.H. for Bradford. County Councillors Association: Miss K. J. Stephenson. Association of Municipal Corporations: Councillor W. J. Loxley. It was announced that Dr. J. J. Jervis, Dr. R. A. Lyster, and Dr. L. H. West were retiring from the Board, and the Board placed on record its regret at their retirement and its appreciation of the valuable services they had rendered during their membership.

Scotland

Anderson College, Glasgow

The annual prize-giving of the Anderson College of Medicine was held in Glasgow on March 13th, under the presidency of Dr. J. Bruce Murray, who said that the usefulness of the institution might be considerably extended to the benefit of Glasgow as a medical centre if more adequate resources were at the disposal of the governors. It was generally realized that vigorous and efficient extramural schools were most helpful and advantageous not only to students of medicine but to the universities themselves. As in other walks of life, competition was undoubtedly helpful in raising the standard of teaching to the highest level. The Anderson College of Medicine had more than justified its position among the permanent institutions of the city, and its classes were recognized for graduation by most of the Scottish and English universities. Many outstanding professors in Glasgow University had first acquired, and proved, their qualifications as teachers in the college. An endowment fund of £10,000 would assist this old and honourable institution to extend its activities, and would relieve the teachers of the heavy contributions at present required to meet the running expenses. The concluding address to the students for the winter session was delivered by Professor J. Graham Kerr on symbiosis; he said that this term was applied to the intimate association of different organisms for mutual benefit. One of the most wonderful symbiotic associations recently discovered was that in which bacteria and fungi set free energy in the form of light instead of heat, as was usual in most organisms. Certain bacteria were used to produce light. The astonishing discovery had been made that the phosphorescent light of various marine animals was really produced by captive bacteria. Two marine fishes, photoblepharon and anomalops, possessed a conspicuous light-producing organ underneath each eye, and microscopical investigation had revealed that this living lamp was composed of numerous tubular arrangements, each containing a culture of light-producing bacteria. Professor Graham Kerr presented the principal prizes to the successful students.

Royal Victoria Tuberculosis Trust

The annual meeting of the Royal Victoria Hospital Tuberculosis Trust was held in Edinburgh on March 11th, under the chairmanship of Sir Robert Philip, who said that for every three deaths from all forms of tuberculosis that occurred in 1887, there was only one death in Scotland at the present day. The work of the Trust was essentially national and Scottish, and patients came to the institution for treatment from all counties in Scotland. Tuberculosis was a very old disease, but the discovery of its cause had been made only fifty years ago by Koch. Since that time much had been learned in regard to it; wherever mankind was crowded together in civilized circles it tended to prevail. More recently they had come to know that for the most part infection was contracted in childhood. The child was the tuberculosis seedling, and childhood was the stage at which the infection should be caught and dealt with. The committee of this Trust had therefore decided to erect a special pavilion for young children at Southfield Sanatorium, and desired to enlist the interest of local authorities by demonstrating that if the infection were taken at this initial stage, the after-tragedy of tuberculosis might be prevented in many cases. With regard to the research work of the Trust, the tubercle-free herd of cattle which it maintained served a double purpose in showing to the farmer that such a farm could be run on economic lines, and in providing a lesson to doctors and students. The aim of the whole country should be to obtain a tubercle-free supply of milk, and the Trust believed that this could be effected with time, patience, and financial support. It did not think that pasteurization should be accepted as the solution of the milk supply. In the coming year the Trust would be called upon to discharge from its small capital between £6,000 and £7,000 towards the extension at Southfield, and it pleaded earnestly for continued support. Dr. Parlane Kinloch, Chief Medical Officer of the Department of Health for Scotland, said that the work done by this Trust had laid down the policy which was followed in Scotland, and the whole world watched the progress of this institution. The annual report draws attention to the fact that at least 42,000 persons are at present affected by tuberculosis in Scotland. It also recalls that while thirty years ago there were only two or three sanatoriums in Great Britain and only one tuberculosis dispensary, there now exist more than 300 sanatoriums and hospitals, with some 500 tuberculosis dispensaries. The report insists that tuberculosis is not diminishing at an equal rate everywhere, for while the mortality from this cause in London, Edinburgh, and New York has fallen remarkably, the figures in other capital cities, such as Paris, Warsaw, and Vienna, continue to be very high. The success attained has been proportionate to the amount of effort. The report holds

that it is of immense importance to realize the primary fact that infection is contracted in childhood, and that tuberculosis infection, once established, continues to exercise an influence on the life of the individual. The hope is expressed that the extension of Southfield Sanatorium, which will provide accommodation for some thirty children, will be ready during the course of the coming summer.

Scottish Nursing Schemes

The annual report of the Scottish Council of the Queen's Institute of District Nursing states that the governing policy of the Scottish Council has been to provide a complete home nursing service for the whole of Scotland. During the past year seventeen new nursing areas have been added to those already working in affiliation with the institute. All these districts have been supplied with fully trained Queen's nurses. As a result of the coming into operation of the Local Government (Scotland) Act in May, 1930, negotiations have been proceeding in numerous counties between the local authorities and the county nursing associations for further developments along the same lines. The Nursing Council congratulates the Nursing Association of the county of Moray on having been the first county area in Scotland to establish a co-ordinated public health nursing service covering the whole county. Arrangements for such a service have been almost completed by the Perthshire Nursing Federation. The council expresses the opinion that the best results are to be achieved where there is, as in these cases, a county superintendent in charge of all the nursing interests in the county. The report states that the payment of an adequate pension for Scottish Queen's nurses on retirement is constantly before the council, which aims at providing an annuity of £52. At present the pension payable is £30 per annum between the ages of 55 and 65, after which the total pension available, including the national pension, is £46.

Ireland

Parsimony in Health Services

At the annual meeting of the Enniskillen District Nursing Society, Dr. L. Kidd, president, said that nowhere in H.M. Dominions was the administration of public health at such a low level as it was in Northern Ireland, excluding Belfast. Public money was freely expended by various Ministries, while many of the public health services, made up of a number of independent units, without any co-ordination or common control, were left to carry on as best they could, in association with voluntary and charitable agencies.

Voluntary Hospitals and the Sick Poor

At the annual meeting of St. Patrick's Nurses' Home, Dublin, Dr T. Gillman Moorhead, President of the Royal College of Physicians of Ireland, said that the suggestion that sick people were sometimes denied admission to hospitals because of their inability to pay was entirely erroneous so far as he was aware. If the poor really were being refused admission, he thought that this fact should be brought to light. He was sure that the public would not tolerate such a state of affairs. Dr. Moorhead criticized the Government for its delay in introducing the Clean Milk Bill, and urged that pressure should be brought to bear for the speedy introduction of this measure. The annual report of the institution stated that, owing to the proposed alterations in the distribution of the funds of the Queen's Institute of District Nursing in Ireland, the committee had not yet received any share of the usual grant from the Irish Diamond Jubilee Fund during 1930, and that the matter was under the consideration of the executive committee.

Meals for School Children

Dr. M. J. Russell, medical officer of health, Dublin City, recently addressed a letter to the Dublin Corporation School Meals Committee, in which he discussed the effect on the health of non-necessitous children through insufficient provision of a hot meal during the school day. In his experience a decent meal was usually prepared in the home soon after one o'clock for the wage-earners, and he thought the most satisfactory arrangement in the city schools, and the most economical for the parents, especially when there were two or more children from one family, would be to extend the interval to enable the children to get to their homes during the time. These children, he thought, would then return to school as willingly as in the morning. Dr. M. M. O'Leary, school medical officer, had pointed out in her annual reports that, as the food they were given in their homes consisted almost wholly of carbohydrates, it was important that the meal provided for them should contain such essential food constituents as protein, fat, and vitamins. In some, but not in all, of the schools which provided free meals these requirements were fulfilled. A hot midday dinner was, she considered, essential for all growing children, as their digestions were impaired by long intervals between meals. A great number of children, other than those of the necessitous poor, had been found on inspection to be suffering from malnutrition, not so much due to lack of food as to lack of the power of assimilation.

Traffic Accidents

The January issue of the *Police Journal*, which is described as a quarterly review for the police forces of the Empire, contains a variety of well-chosen and informative articles. Perhaps the most topical from the medical point of view is a discussion of the human element in traffic control, by Major-General W. R. E. Murphy, deputy commissioner, Civic Guard, Irish Free State, who points out that, despite legislative reforms and improvements in transport facilities, the number of street accidents continues to increase steadily from year to year. This, he thinks, may be attributed to the fact that the measures instituted to eliminate the causes of accidents have failed to appeal to the intelligence of street passengers, with the result that real co-operation between pedestrians, motor drivers, and traffic police is almost entirely lacking. What is required in his opinion is a complete code of rules of the road expressly designed to meet the requirements of modern traffic conditions, both vehicular and pedestrian. To impose additional restrictions on motorists without imposing corresponding restrictions on pedestrians is not likely to reduce the accident rate, since a large percentage of traffic accidents can be traced to the negligence of foot passengers. Some figures are quoted to support this contention. An analysis of the fatal traffic accidents that occurred in Dublin during 1929 revealed that 45 per cent. were caused through the fault of pedestrians; while statistics compiled by the Safety First Council in Great Britain from returns of accidents furnished by coroners indicated that 48 per cent. were due to the carelessness of passengers other than motorists. A suggested code of rules, based mainly on proposals put forward by the Civic Guard at the Traffic Commission held in Dublin in 1927, is incorporated in the article.

Correspondence

GLYCERIN AS A GERMICIDE

SIR,—Perusal of the series of letters under the heading "Glycerin as a surgical dressing" which have recently appeared in the *Journal* would seem to indicate that the various writers are unaware of the fact that glycerin, *when diluted to the extent of about 50 per cent. with water*, is an efficient germicide, especially at body temperature.

It may therefore be of interest to recall the fact that it was the discovery of this germicidal power of glycerin, about forty years ago, that rendered possible the introduction of a bacteriologically pure anti-small-pox vaccine, which, by reason of its method of preparation, I termed "glycerinated lymph."

Subsequently, the late Dr. F. R. Blaxall became associated with me in further experimental work on this subject, as an outcome of which we read a joint paper at the meeting of the British Association at Liverpool in 1896, recording the results obtained. In this paper we showed that, in culture media such as peptone beef broth, glycerin present to the extent of about 40 per cent. in the cold, prevented development of, and eventually killed out, not only all staphylococci experimented with, but also streptococci, and the bacilli of tubercle diphtheria and enteric fever. This action of glycerin was considerably hastened on exposure to body temperature. The only organisms that we found capable of resisting the action of this same percentage of glycerin longer than a month were the spores of the common hay bacillus, spores of *B. mesentericus vulgatus*, the common pink yeast, and *B. coli communis* when kept in the cold.—I am, etc.,

Athenaeum, March 15th. S. MONCKTON COPEMAN.

AN UNUSUAL MENTAL ABNORMALITY

SIR,—I have recently had under treatment a man who has for thirty years suffered from a rare form of sexual perversion, but one which it is desirable that doctors, schoolmasters, and others should know about. Since the age of 11 years he has derived sexual satisfaction from tying himself up or getting someone else to tie him up. He has jealously guarded his secret, never letting his accomplice (when he had one) know the real motive for the tying up, but pretending that it was a game. Gradually the perversion became more and more compulsive, and more and more difficult to control, and the object in view was to tie himself up so tightly as to be practically helpless. My patient writes:

"Though I always took care to leave some kind of a loophole to escape by, I made it as difficult as I dared (for example, a knife placed in a difficult place to reach). I was only discovered once, and that when I was about 14, at a public school. I had a narrow escape at a camp during the war, when I succeeded in handcuffing myself with a chain, and nearly could not escape."

The tying-up game was practised by the patient's dormitory at his private school, when he was about 11, and gave the trouble a considerable impetus. But deep mental analysis revealed beginnings of the abnormality in very early years, based upon the masochistic component of the sexual instinct.

Had this patient received psychotherapeutic treatment in his youth he would have been saved years of most severe mental torture. The compulsive nature of the tendency makes it dangerous, as well as painful, to the sufferer.

It is clear that schoolmasters in boarding schools should be acquainted with the possibility of such a perversion as this, and should know how to deal with the tying-up game.—I am, etc.,

WILLIAM BROWN, M.D., D.Sc., F.R.C.P.,
Wilde Reader in Mental Philosophy, University of Oxford.

March 16th.

STATUS LYMPHATICUS

SIR,—One would have thought that if any field of human endeavour was to escape the craze for settling things by committees that field was medicine. And so I read with some misgiving, in the last number of the *Journal*, that a Status Lymphaticus Committee had decided that there was no such thing as the subject-matter of its investigation.

It did not appear whether any forensic pathologists were on this committee. If these were not adequately represented the pronouncement would in any case be devoid of authority, for forensic pathologists alone have any wide experience of cases of sudden death among the apparently healthy.

This is not the place to give reasons why hyperthymism (as it is perhaps better called) will survive this blow, nor for my present purpose does it matter in the least whether the condition exists or not. What I do suggest is that the profession ought to look askance at the re-institution of mediaeval methods of arriving at the truth. A committee once decided that the earth does not move. *Eppur si muove.*—I am, etc.,

London, W., March 14th. TEMPLE GREY.

DISSEMINATED SCLEROSIS RESEARCH

SIR,—In the *Journal* of March 7th (p. 425) there is a joint letter from Dr. Braxton Hicks and Dr. Hocking, in which they make reference to the research work formerly carried out by me at Westminster Hospital. They state that they have "observed a spherule" in spinal fluid from disseminated sclerosis patients. Presumably they mean to say that they have observed a spherule in cultures of cerebro-spinal fluid of disseminated sclerosis patients.

It is evident to anyone conversant with the elementary principles involved that, when the optical system employed in my own work is used, all bodies below a certain size appear spherical, hence it is puzzling to read that Drs. Braxton Hicks and Hocking "are not prepared to say that this [disseminated sclerosis] is the only nervous affection in which the appearance can be seen." It is not clear whether they mean that they see such spherical objects (which, of course, can be demonstrated in any material, including uninoculated media), or that they see an appearance characteristic of disseminated sclerosis. They state that they have been unable to confirm a number of my findings, but it would appear from their letter that they have entirely failed to confirm any of my findings. Obviously their results are in no way related to my own, for I have never throughout my work claimed that "a spherule" is diagnostic of disseminated sclerosis. On the contrary, I have always endeavoured to emphasize the error of attaching diagnostic importance to the appearance of spheres alone in a fluid medium. I have pointed out, verbally and in my original publication, that in cultures of cerebro-spinal fluid from cases of disseminated sclerosis a certain sequence of events occurs in which a small granular form is associated with other bodies (spheres) of essentially different character, and that it is this appearance of spheres with granules attached, the characteristic colonies formed, and changes in successive stages of growth, which are the diagnostic

features. Such characteristic changes can only be observed in cultures made with solid medium. Throughout my original publication the word "spherule" is never used, lest the erroneous impression should be created that the presence of spheres in cultures is of diagnostic importance. I have never expressed the opinion, verbally or in print, that "a spherule" is a living virus. I quote my original words on the subject in March, 1930: "It would appear that a study of the virus described in this paper affords proof of the existence of a body, less than 0.2μ in diameter, which is actually living." Obviously I am not referring to "a spherule" or spheres as the virus, since they of necessity must be larger than 0.2μ.

I emphasize these matters because from a clinical point of view they are extremely important in that the vaccine treatment formerly carried out by Sir James Purves-Stewart, in which he used vaccines prepared solely by myself, had as its basis this conception of the whole problem of cultural work in disseminated sclerosis. Clearly mine is a totally different conception from that held by Dr. Hicks and Dr. Hocking as disclosed in their letter.—I am, etc.,

London, N.W.3, March 17th. KATHLEEN CHEVASSUT.

SIR,—Dr. Halley Stewart is concerned to obtain for Miss Chevassut a fair judgement upon her work in connexion with disseminated sclerosis. There should be no difficulty in this provided that those who make public pronouncements on the matter first ascertain the facts and then state them correctly. Unhappily, I find myself unable to agree that his letter fulfils these elementary requirements. In his endeavour to place the position in its true perspective, Dr. Halley Stewart submits four statements of "fact." An examination of these reveals them to consist of two expressions of opinion, an inaccurate account of two matters of fact, and a final paragraph concerning the formation of a Halley Stewart laboratory, which has no bearing on the validity or otherwise of Miss Chevassut's claims.

Let me take the relevant "facts" seriatim.

1. *That Miss Chevassut is not responsible for a failure of other observers to confirm her findings.*—This, surely, is a wholly irrelevant proposition, as a purely hypothetical illustration will show. If I claim to behold a unicorn in Parliament Square, and none of the bystanders can see it, a not unlikely explanation will be that in fact there is no unicorn. In these circumstances, for me to asseverate that I am not responsible for their failure to confirm my observation would be a frivolous gesture. Responsibility clearly rests with me either to take steps to substantiate my claim or to abandon it.

2. *That Miss Chevassut alone is conversant with the technique of her research, and alone is capable of preparing the appropriate "vaccine."*—Even if we allow that this hypothesis was once true, it is certainly not an eternal verity. To continue indefinitely to reiterate it is to make a mystery where none need be, for there is no bacteriological or biochemical technique that a competent worker may not acquire. Dr. Halley Stewart seems to imply that even now there is no one capable of assessing Miss Chevassut's work or of repeating it. I note that he asks for fair judgement. By all means let us be fair to everyone concerned, including Dr. E. A. Carmichael, who, at the request of the Medical Research Council, repeated this work, but was unable to confirm the results claimed for it. No informed critic will dispute that he is an eminently competent observer. His work was carried out under the same roof as Mr. Barnard's laboratory, and he enjoyed to the full all those advantages of technical advice and assistance that were available to Miss Chevassut.

3. *That Miss Chevassut's inability to obtain positive cultures from a series of unlabelled specimens of cerebro-spinal fluids sent from various hospitals was due to a neglect to meet certain conditions previously laid down by her as essential to success—namely, that the fluids should not be transported before culturing.*—Here Dr. Halley Stewart is under a complete misapprehension. When, with Miss Chevassut's concurrence, the test in question was planned, she sent me her requirements in writing, and proposed, in addition to the culturing of fluids, to prepare vaccines for treatment. These requirements were fully met, and the objection that the conditions of the test precluded success was not raised until after the event, and when it was clear that the test had proved negative. These facts indicate that Miss Chevassut did not hold the views on this matter attributed to her by Dr. Halley Stewart, and indeed it is impossible that she should have held them, since much of the material from which her original positive results were obtained was transported from private nursing homes to her laboratory, under conditions not dissimilar from those of the test series.

Dr. Halley Stewart is also misinformed when he states that no positive culture was obtained from any of the test fluids. Miss Chevassut reported the culturing of the "appearance" known as the "spherula insularis" from a fluid that proved to have been obtained from a case of rheumatic chorea.

In these circumstances the inadequate and misleading character of Dr. Halley Stewart's exegesis is manifest, and I submit that the following considerations place the present position of this investigation in the true perspective he desires: (1) that a competent observer, working under ideally favourable conditions, has been unable to corroborate the existence of a "spherula insularis"; (2) that Miss Chevassut herself has found it impossible to confirm her original results when working with a test series of specimens of cerebro-spinal fluid taken from cases of which the clinical diagnosis was unknown to her; and (3) that having been afforded another opportunity of repeating the test under her own conditions in the laboratory of the National Hospital, Miss Chevassut has declined the invitation, and has vouchsafed no reason for her refusal.

It seems expedient at the present juncture to formulate these points clearly, for I believe that the only possible result of Dr. Halley Stewart's letter, if it be allowed to go uncorrected, will be to deepen still further the mystery that clings so closely to this research.—I am, etc.,

London, W.1, March 16th. F. M. R. WALSHE.

GENETIC RELATIONSHIP BETWEEN CRETINISM AND HYPOTHYROIDISM

SIR,—Mr. C. J. Bond in his letter (March 7th, p. 423) raises a question of fundamental importance. I hope his question will receive attention from those who have had an opportunity of observing the offspring of cretins who have been restored to normal efficiency by thyroid feeding. An opportunity of this nature must be very rare, otherwise some records would be now available. Apart from the known fact—which Mr. Bond mentions—that thyroid feeding activates the cerebral neurones and restores the cretin ament to a degree of normality, another question may be asked: Does thyroid feeding also restore reproductive function? If this latter question be answered in the affirmative, then, what results would be expected from the mating of restored cretins, and how would this help us to understand whether the thyroid deficiency was due to some variation in the genetic constitution or to environmental factors?

Supposing two restored cretins mated and had several stinous offspring, and that this observation could be nfirmed by several other instances of the same kind in ner environments, then it could be inferred with some nfidence that the thyroid deficiency was due to a varia- n in the genes and not to environmental factors—that e cretinism was due to recessive factors in the Mendelian ase. Such an example must be exceedingly rare, so re as to be negligible for practical purposes. The most mmon mating would be restored cretin with normal, d the latter would be dominant as regards thyroid iciency, so that the offspring would all be normal, unless those instances where the normal was heterozygous for yroid efficiency when a cretin might appear in the family a Mendelian recessive.

So far as the thyroid gland is concerned many of these uestions can be and have been answered by animal eeding experiments, but what Mr. Bond has in mind is e mental status of the human being—he calls it the europsychic condition. The question then really comes this: Can all the factors, genetic and environmental, hich are causative of the mental constitution of human eings be disentangled and estimated with some degree accuracy without human breeding experiments? I do ot see that they can. Observation and record are helpful p to a point, but only crucial experimentation will settle ie wrangles over the influence of heredity and environ- ent in the constitution of man.

Mr. Bond also asks about the genetic relationship of yperthyroidism. This is more hopeful because the con- ition is common, and does not interfere with the function reproduction. I have at present in my practice a other and daughter, both suffering from hyperthyroidism. he daughter showed severe symptoms two years ago, hen she was 24, and the mother a year ago, when she as 54. There has been no change in the environment, nd the dietetic habits have been unaltered, so that there ay be some genetic relationship, but, on the other hand, may be mere coincidence that the thyroid gland in both as become abnormally active.

I hope Mr. Bond's letter will stimulate some medical en to study the families, and record their observations n these cases of hypothyroidism and hyperthyroidism nd the associated mental states.—I am, etc.,

Warrington, March 8th. J. S. MANSON.

TREATMENT OF PYLORIC OBSTRUCTION

SIR,—In the *Epitome* for March 7th I notice that Dr. W. De Scriver has described, in the *Canadian Medical Association Journal*, a case of pyloric obstruction relieved by medical treatment.

While at the North Middlesex Hospital I had a similar case of well-marked pyloric obstruction, which also responded to medical treatment. The patient, a man aged 50, was admitted in a very weak and dehydrated condition. He gave a typical history of, and showed on examination unmistakable signs of, pyloric obstruction. The radiologist reported marked pyloric obstruction due to old duodenal ulcer. Operation was advised, but this was refused. There was therefore nothing left to do but to treat the case medically. Atropine was administered, and the stomach was washed out. Frequent rectal feeds of glucose and saline were given and nothing was allowed by mouth for two days. After the second day he was given small feeds of egg albumen and water every three hours by mouth. Rectal salines were continued. The feeds were gradually increased, and after a week the patient showed marked improvement in general health. The stomach was *x*-rayed three weeks after admission, and was then found to empty completely at the normal rate. The patient was discharged in excellent health and was able to resume his employment. At a later date he was operated on, and a chronically diseased gall-bladder, which was adherent to the duodenum, was removed.

In this case the obstruction was probably due to spasm of, and oedema around, the pylorus, which cleared up completely after rest and suitable treatment. While investigating a large number of cases of duodenal ulcer, I was struck by the number of patients who showed on *x*-ray examination a twenty-four hours' "hold-up" in the stomach, due to some degree of pyloric obstruction, and who responded well to medical treatment.

In severe cases of pyloric obstruction one does not feel justified in delaying operation until medical treatment has bettered the patient's general condition. In lesser degrees of obstruction, found after *x*-ray examination, medical treatment should be tried before operation is advised.—I am, etc.,

Edinburgh, March 9th. J. R. MURDOCH.

TREATMENT OF VARICOSE ULCERS

SIR,—The recent correspondence in the *British Medical Journal* on the treatment of varicose ulcers tends to show the futility of using topical applications alone and the necessity for employing a mechanical support in conjunction with the injection treatment if one is ever to expect permanent cure of this type of ulcer. That the injection treatment of any existing varicose veins is of paramount importance is shown by the fact that ulcers having no injectable veins (this type might be termed "capillary varicose ulcers") are not only very difficult to cure, but 10 to 15 per cent. recur, and can only be kept in check by the constant use of some form of support.

Evidently all do not use the same material for this support; some advocate and are warm supporters of elastoplast bandages, others prefer plain or flannel bandages. Opinions also differ as to how they should be applied and the length of time they should remain before being changed. The consensus of opinion, however (and rightly so), is: (1) for their firm application, and (2) for infrequent changing. But no matter what form of material is used, success depends entirely upon the correct method of applying it. Prior to his use of elastoplast bandages, Mr. Dickson Wright obtained by the use of strapping results that can hardly be excelled by the more elaborate methods now in vogue. There is a right and a wrong way of applying strapping, even more so perhaps in the application of a bandage; this is the principal reason why these cases should not be treated by inexperienced persons, either in hospital or in private practice, any more than intravenous injections should be allowed to be given for the cure of varicose veins (in out-patient departments) except by persons proficient in this branch of surgery. If this were adhered to and these diseases considered as serious, not only as regards the general health of the patient but also for his earning capacity, fewer complications would be seen and more rapid results obtained. Unfortunately these obviously grave pathological conditions are regarded by the laity—and by many of the profession—as of minor importance, and therefore proper cases for dressers or nurses to attend to. One cannot help feeling with regard to intravenous injections that under no circumstances should they be given by anyone but the surgeon himself or by a fully trained assistant conversant with the technique and alive to the possibility of complications arising from the use of the solutions of the moment, none of which are free from risk of causing untoward local or general reactions. The importance of this cannot be too strongly stressed so as to prevent the patient's local or general condition, during treatment or subsequently, from becoming worse than before.—I am, etc.,

London, March 8th. T. HENRY TREVES BARBER.

RTALITY IN ACUTE APPENDICULAR DISEASE

SIR,—In the recent discussion in the *Journal* on the causes of the post-operative mortality in acute appendicitis, no reference has been made to acute blood infection, which I am convinced, from personal experience, is a not infrequent cause of death, especially in young persons. I have frequently drawn attention to this in the *Journal* and elsewhere, but either it remains generally unrecognized or the symptoms are attributed to another pathological cause, such as "delayed chloroform poisoning" or "acidosis."

The symptoms are characteristic and pathognomonic. After a period of from twenty-four to forty-eight hours from the operation a sudden change for the worse occurs; the face becomes pallid, temperature rises, pulse becomes very rapid, there is marked restlessness with very short periods of apparent sleep, interrupted by a shrill "meningeal" cry, delirium is followed by coma, and death generally occurs within twenty-four hours. There are no abdominal symptoms such as distension, vomiting, etc.; in fact, the abdomen is generally soft and sometimes retracted. The symptoms are suggestive of an acute cerebral meningitis. In every case in which these symptoms have appeared a culture of *Strep. faecalis*, either pure or with *B. coli*, can be obtained from the blood.

Blood infection has occurred at the time of operation, either from manipulating or crushing acutely infected tissue before sufficient antibodies have developed to produce blood immunity. It is especially apt to follow operations performed from the second to the fifth day after the onset of the disease.—I am, etc.,

HERBERT H. BROWN, M.D., F.R.C.S.

Ipswich, March 16th.

SIR,—If, in the last sentence of his letter in the *Journal* of March 14th (p. 471), Professor Wilkie had emphasized the grave significance of a rising pulse rate as shown by quarter-hour records, the present-day teaching of the symptomatology of acute intestinal obstruction would have gained much in authority, and a clear picture of the necessity for an immediate surgical operation in these cases would have been impressed upon all. Afebrile epigastric pain, vomiting, and a steadily rising pulse rate as shown by quarter-hour records—these three associated symptoms ought to raise in the mind of every educated observer the suspicion of acute intestinal obstruction, and if immediate laparotomy is carried out many of the three thousand odd deaths from acute appendicular disease will be prevented.—I am, etc.,

Glasgow, March 16th. W. RANKIN.

SERUM ANAPHYLAXIS

SIR,—I have read with interest Dr. Margaret Wylie Thomas's comments on the cases of serum anaphylaxis, published in a memorandum in the *Journal* of February 7th. Although I agree that it is the first dose of serum that causes sensitization, and that this rarely develops before the tenth day, yet I strongly disagree with the general conclusion reached by Dr. Thomas that "the interval between the first injection and the proposed additional dose should not be greater than nine days." This is only correct if no intervening doses are given.

In Choyce's *System of Surgery* (1927, i, 3) Professor John W. H. Eyre writes:

> "The injection of a fair-sized second dose of serum during the incubation period results in the production of a condition of anti-anaphylaxis which again persists for an indefinite period."

This can surely be taken as a "commonly accepted idea." It was on this idea that the two cases were treated. In each case the interval between the first dose of serum and that causing the anaphylaxis was considerably more than ten days, but, according to t quotation, the intervening doses of serum sho caused the condition of anti-anaphylaxis. The anaphylaxis did occur was the reason for the cases.—I am, etc.,

Liverpool, March 16th. [illegible]g.—Here Dr.

CLOSED DRAIN[illegible]mplete misapprehensio[illegible]ssut's concurrence, the test

SIR,—In th[illegible] she sent me her requirements George Rol[illegible]ed, in addition to the culturing method [illegible]accines for treatment. These requir He trea[illegible] met, and the objection that the co his tec[illegible]st precluded success was not raised un[illegible] Dr. [illegible]t, and when it was clear that the t*Journal* of March 7th. [illegible] discharge of pus into a beaker of antiseptic solution. T him belongs the honour of devising this method.—I am, etc.,

Bradford, March 12th. WILLIAM MITCHELL, M.B.

THE ENIGMA OF THE CHILBLAIN

SIR,—If one has a disease one learns a good dea about it, and I hazard a guess that Dr. Izod Bennett' interest in chilblains is an impersonal one. They are unfortunately, a major complaint of mine, and I rea Dr. Hallam's article appreciatively and sympathetically I have learned to thole this trouble in silence, and it i only subsequent correspondence which has led me t address you.

There is, according to the pharmacologists and academi physicians, no such thing as intestinal toxaemia, and w who suffer from this phantasm nurse it secretively withi our bellies—an *ignotum quid*—and pander to it by die and the adherence to a few simple rules of life. I com of a family whose intestines become assertive toward middle life, and who have a tendency to fibrou rheumatism and the development of cataract about th same time. Cold hands and feet are part of their com plaint; but I am the solitary sufferer from chilblains and this trouble appeared only after an attack o dysentery contracted during the war. My age was then 31

It is evident that cold is the culminating factor in th production of the chilblain, but unless the real causativ factor exists in the body, no degree of cold will caus the condition to develop. Dr. Leonard Williams's remark in your issue of February 21st apply *in toto* to myself and acute attacks of chilblains can be alleviated within twenty-four hours by a purge and rigid attention t diet. I have often wondered if the condition was a bacterial embolic one, for I am familiar in my own perso with waves which come and go, and leave periods o relative immunity. My first attack consisted of many very small areas on the hands and fingers, which wer diagnosed by several physicians (in a cold April) a mosquito bites!

The taking of calcium does help many people, and help me to an appreciable extent. It gives me, too, a feelin of greater fitness and well-being. Ultra-violet light wil cure troublesome attacks, and irradiated milk is helpfu in the diet. To what extent the action of these latte items depends upon their action on calcium metabolism is doubtful. I have read somewhere that they affect th *p*H of the intestinal contents, and, while this doubtles plays a part in the absorption of calcium, it conceivabl affects the bowel in other ways. Finally, a holiday unde stimulating mental conditions will often work wonders—if one does not forget to adhere to the diet which one' hypochondriacal bowels demand.

As I do not desire to advertise my infirmities, enclose my card, and subscribe myself

March 3rd. AGRESTIS.

Obituary

DAVID HEPBURN, C.M.G., M.D., C.M.

Emeritus Professor of Anatomy, University of Wales

The genesis of David Hepburn, whose death on March 9th was [illegible] reticism was due to [illegible] week's issue of the *Journal*, had been [illegible] Such an example must be [illegible] cal education in Cardiff for as to be negligible for practical purposes before that in Edinburgh. non mating would be restored cretin was 859, and received his the latter would be dominant as regard here he graduated iency, so that the offspring would all be normal three years later he hose instances where the normal was heterozygote of Surgeons of oid efficiency when a cretin might appear in the twinning the gold Mendelian recessive. [illegible] After holding far as the [illegible] Royal Infirmary, he was appointed monstrator of anatomy under Sir William Turner; om 1885 to 1903 he was principal demonstrator and cturer on regional anatomy, and was then elected ofessor of anatomy at University College, Cardiff. To s devoted service the Welsh National School of Medine owes much. He was a very popular teacher, as ell as a sound administrator, and his appointment in 920 to be dean of the Faculty of Medicine was warmly elcomed. Characterized by clarity of thought and of xposition, he was able to simplify for his students some f the more difficult parts of anatomy. He contributed Cunningham's *Textbook*, and was the author of arious original papers on arthrology and the comparative anatomy of the muscles of the limbs.

Professor Hepburn represented the University of Wales n the General Medical Council from 1912 to 1927. He was a member of various scientific societies, including he Anatomical Society of Great Britain and Ireland, of which he was a past-president; the Royal Physical Society of Edinburgh, the Scottish Microscopical Society, he Scottish Natural History Society, and the Cardiff Medical Society, of which he was at one time president. He was a member of the General Committee of the British Association, and of the Advisory Council on Medical Research. He had held the posts of examiner to the Conjoint Board in England, and the Universities of Edinburgh, Oxford, Liverpool, Sheffield, and Leeds.

During the war he was in command of the Third Western General Hospital at Cardiff; he was created C.M.G. in 1917, and became honorary surgeon-colonel and lieutenant-colonel. He was also a Knight of Grace of the Order of St. John of Jerusalem. His great gift for organization proved of outstanding value in this connexion, and he was warmly commended by the then Prime Minister. Although his resignation from the professorship fell due in 1924, he was then, and again on a subsequent occasion, invited to retain it, only retiring in 1927 amid expressions of general regret. He is survived by his widow, one daughter, and one son, who is medical superintendent of the Hamadryad Seamen's Hospital, Cardiff. His funeral, on March 12th, was attended by many representatives of the various organizations he had served so well during his life, and by a large number of those whose warm friendship he had won by his leadership, unselfish devotion, and lovable personality.

ARTHUR HEYGATE VERNON, F.R.C.S.

Consulting Surgeon, Royal Victoria and West Hants Hospital

By the death of Mr. A. H. Vernon, Bournemouth has lost one of its most distinguished and gifted townsmen; he was beloved by his patients and respected by all who knew him.

Arthur Heygate Vernon was educated at St. George's Hospital, and took the M.R.C.S. in 1886, the L.R.C.P. in 1887, and the F.R.C.S. in 1890. At St. George's he was demonstrator of anatomy and physiology, and house-surgeon, and was appointed assistant in the orthopaedic and ophthalmic departments. On coming to Bournemouth he soon showed himself to be a man of more than ordinary ability, and quickly established a reputation as an excellent surgeon; he also took an active part in town affairs, and was made a J.P. of the borough. He was for many years surgeon to the 7th Hants Regiment (T.A.), retiring with the rank of lieutenant-colonel, and receiving the Territorial Decoration. He had long been surgeon to the fire brigade, and took an energetic part in the local branch of the British Legion and the St. John Ambulance Brigade and Association; he was also a prime mover in the building of the Little Theatre, Bournemouth.

At the time of his death Vernon was treasurer of the Bournemouth Medical Society, of which he had been president. In the British Medical Association he was past-president of the Dorset and West Hants Branch, and had occupied the chair of the Bournemouth Division. He was also a Fellow of the Royal Society of Medicine, but of all his many and various interests the hospital occupied the first place in his affections, and it is through his indomitable perseverance that the Royal Victoria and West Hants Hospital occupies the position it does to-day. By the passing of Arthur Heygate Vernon the profession has lost a distinguished son and a man of sterling worth, whose rugged but kindly personality will ever be remembered with affection and regard.

S. J. ROSS, M.D.

Late Surgeon, Bedford County Hospital

Stephen John Ross, M.D., son of the late Rev. Dr. Ross of Dallas House, Lancaster, died after a very short illness at Stoke Ferry, Norfolk, on February 14th. He was educated at the Royal Grammar School, Lancaster. He commenced his medical studies at the Liverpool Medical School, his principal teachers being Dr. Caton, Sir W. M. Banks, and Dr. Rushton Parker. He graduated M.B., Ch.B. at Victoria University, and subsequently held the posts of resident house-physician, house-surgeon, and assistant in the ophthalmic department of the Royal Infirmary, Liverpool, and that of medical officer of the Lock Hospital, Liverpool. He was medallist in forensic medicine and toxicology, prizeman in obstetrics, and held the honour certificate in surgery.

In 1896 he was elected house-surgeon to the Bedford General Infirmary. It was during his house-surgeoncy that the old infirmary was replaced by the splendid existing institution, and its name changed to that of the Bedford County Hospital. The new hospital was opened in 1899, and at the special request of the board of management Ross remained longer than he otherwise would have done in order to superintend the removal of patients from the old to the new buildings. After a short absence in the North he returned to Bedford, entering into partnership with the late Dr. Rowland Coombs, with whom, and with his son Martin Coombs, he remained until his retirement. In 1900 he was elected assistant surgeon, and in 1920 surgeon, to the County Hospital, retaining that post until his retirement under the age limit in 1930.

As to his work at the hospital, Mr. Arnold Whitchurch, chairman of the board of management, writes: "Dr. Ross was an example of what 'honorary' really means in connexion with the medical staff of a hospital. No man gave more fully of his time. Every day he would visit his patients, and eight to ten hours weekly was the usual thing, and often still longer hours in emergencies, and all freely given—the thought of payment was abhorrent to him. For thirty years he gave *himself*. Although rarely present at the board meetings, which

ORTALI during his operating hours, he gave great help
SIR,—Ing the constitution, and there was no one more
causes o us in carrying it out than himself. His passing
citis, r great shock to us all." His senior colleague on the
whic tal staff, Mr. W. Gifford Nash, writing in the same
infr ain, refers to the assistance given him in operation
h ork, both at the hospital and in private, and the
complete harmony of their work together.

Despite an unusually laborious professional life, Ross made time to take an active interest in various medical societies. He was president of the Bedford Medical Society in 1916, and made many concise contributions in the way of papers and in discussions at the meetings. He held office in the British Medical Association, and was chairman of the old Beds and Herts Division and president of the South Midland Branch, and for many years served on the committee of the Bedford Trained Nurses' Institution and Nursing Home. When the Insurance Acts came into being, and local practitioners were reluctant to accept service, Dr. Ross had a personal interview with Mr. Lloyd George, and, though he disapproved of the Acts, himself accepted service under them and for several years gave them his loyal support. He had the mind, if not the training, of a lawyer, and for many years was on the council of the Medical Defence Union. He thoroughly enjoyed their meetings and the unravelling of various ethical problems. Had he gone to the Bar he would probably have succeeded there as brilliantly as he did in medicine. He wrote very little, but was a laborious compiler of records, and had he been spared he would no doubt have enriched medical literature with gleanings from his great store of clinical notes. He was widely read, both in ancient and in modern literature. An ardent botanist and lover of his garden and greenhouse, the weird in plant life specially appealed to him; he was a valued member of the Bedford Arts Club and chairman in 1911, rarely missing any of their Saturday evening meetings, and lecturing there from time to time on his favourite plants and the scenes of his few and brief holidays in the Isle of Man and Lakeland. His premature death after such a very few months of retirement has robbed the profession of a rare personality, and us who knew him so well of a true, sympathetic, and most self-sacrificing friend. He leaves a widow and two children to mourn his loss.

Medico-Legal

"NATURE CURE" PRACTITIONER AND WOMAN'S DEATH

An inquest was held at New Barnet on March 13th on the death of Mrs. P. G. Pickett, aged 35, of Addington, East Croydon, who had been undergoing treatment by Mr. Victor Dane, described as a "nature cure" practitioner, of New Barnet. It appeared from the evidence that on the day of Mrs. Pickett's death Mr. and Mrs. Dane had gone away on a day's visit, and the death took place in their absence.

Mr Pickett, the widower, stated that his wife had at various times consulted doctors, who simply told her to carry on with the diet which she was taking for indigestion; this consisted mainly of fruit, salads, and nuts. In February she went to New Barnet to take a course of "nature treatment" under Mr. Dane's direction. On one occasion when her husband visited her, she told him that she was very happy and felt better for the treatment she was receiving, but on the following day he had a message to say that she had died. He added that she disliked doctors, and had resisted entreaties to obtain medical advice.

In evidence Mr. Dane said that he was a doctor of science, with an American degree, for which, however, he had not paid any fees. When he first saw Mrs. Pickett he suspected arthritis, but later diagnosed anaemia, for which he treated her. He had never described himself as a doctor. He had wanted to call in a fully qualified medical man because he doubted the cause of the illness and desired to avoid possible future trouble.

Dr. O'Callaghan of New Barnet, who had made a post-mortem examination, stated that the cause of death was advanced tuberculosis of the lungs. The body weighed only 5½ stone; the normal weight for the woman's height was 9 stone.

The jury returned a verdict of death from natural causes, and stated their opinion that medical aid should have been called in several days before Mrs. Pickett died; also that, considering the undertaking given by Mr. Dane, and the fees paid him, gross carelessness was shown in leaving the patient for a whole day without efficient help. The coroner (Mr. T. Otaway) said that he entirely agreed with the rider.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

At a congregation held on March 13th the following medical degrees were conferred:

M.D.—J. H. Doggart.
M.CHIR.—N. R. Barrett, E. D. Moir.
M.B., B.CHIR.—M. E. Albury.
B.CHIR.—J. G. Wigley.

The Senate has resolved to confer honorary doctorates upon Professor John Scott Haldane, C.H., M.D., F.R.S., Director of Mining Research in the University of Birmingham, and Augustus Moore Daniel, M.A., M.B., Ch.B., Director of the National Gallery.

UNIVERSITY OF LONDON

The following have been recognized as teachers of the University in the subjects indicated:—Guy's Hospital Medical School: Dr. F. A. Knott (pathology); London Hospital Medical College: Sir Robert Stanton Woods (physical medicine); Middlesex Hospital Medical School: Dr. Lionel E. H. Whitby (bacteriology).

The regulations for the academic diploma in public health (Red Book, 1930-31, pp. 467 to 469) have been amended: (1) By the insertion after the words "twelve calendar months" in the second paragraph, page 467, of the words "(or an academic year of whole-time study covering a period of not less than nine calendar months)." (2) By the substitution for the fourth paragraph, page 467, of the following:—"Part I. A course of practical instruction, during not less than 280 hours, in the following subjects: (*a*) bacteriology and parasitology (including immunology, serology, medical entomology, etc.), especially in their relation to diseases of man, and to those diseases of the lower animals which are transmissible to man; (*b*) chemistry, physics, radiology and electrology in relation to public health; (*c*) physiology and biochemistry in their application to nutrition and hygiene; (*d*) meteorology and climatology in relation to public health." (3) By the substitution for "80 hours" in the first line of the fifth paragraph, page 467, of the words "120 hours." (4) By the deletion of the number of hours after each section of Part II of the course, page 467, and of the words: "(The numbers indicate the normal proportion of time to be given to each subject)." (5) By the substitution for the last sentence of Section (ii) of the first paragraph on page 468 of the words "At least 24 daily attendances of not less than 2 hours each shall be required." (6) By the insertion at the end of the first paragraph on page 468 of the following: "Instruction in subjects (*a*) to (*f*) should include attendance at the centres, clinics, institutions, and premises concerned."

Copies of the regulations for the diploma in public health for external students can be obtained on application to the external registrar.

Professor M. E. Delafield has been appointed the representative of the University at the fifth Imperial Social Hygiene Congress, to be held in London in July.

UNIVERSITY OF EDINBURGH

The Senatus Academicus has resolved to confer the honorary degree of LL.D. on Sir George A. Berry, F.R.C.S.Ed., M.P. for the Scottish Universities and formerly lecturer in ophthalmology in the University of Edinburgh, and on Sir Walter Morley Fletcher, M.D., F.R.S., secretary of the Medical Research Council.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

Council meeting was held on March 12th, when the Presi-nt, Lord Moynihan, was in the chair.

Diplomas and Licences

The diploma of Fellowship was granted to Edward Grainger ir, the Bernhard Baron Scholar, who has now complied th the by-laws. Diplomas in Ophthalmic Medicine and rgery were granted, jointly with the Royal College of ysicians, to eighteen candidates. Licences in Dental rgery were granted to twenty-one candidates.

Appointments

Mr. Gwynne Williams was re-elected a member of the Court Examiners for five years. Mr. Fagge was appointed as legate to the centenary celebrations of the Leeds School of edicine, to be held on June 30th and July 1st. Sir Holburt aring was appointed as representative to the Quinquennial ngress of the Universities of the Empire, to be held in ndon and Edinburgh on July 3rd and July 7th to 10th.

International Orthodontic Congress

The College will give an evening reception to the members of ie Second International Orthodontic Congress, to be held in ondon from July 20th to 24th.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

t the monthly meeting of the Royal Faculty of Physicians nd Surgeons of Glasgow, held on March 2nd, David Mackay lart and Margaret Taylor Tindal were admitted, after exam-nation, as Fellows of Faculty.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

his week the House of Commons heard the statement of he Secretary for Air on the Air Estimates, and further onsidered those for the Navy. The committee stage of he Representation of the People Bill was continued on larch 16th. The House then rejected by 246 votes to 42 Clause 4, which proposed to abolish the University onstituencies in Great Britain and Northern Ireland. Iajor Ross moved the rejection of the clause, and Dr. Sinclair, as representing Queen's University, Belfast, econded. The following members voted against the Government in the division: Dr. Vernon Davies, Dr. Elliot, Dr. Fremantle, Sir E. Graham-Little, Dr. Morris-Jones, and Dr. Sinclair. For the Government there voted: Dr. Addison, Dr. Morgan, Dr. Hunter, Dr. Salter, and Dr. Drummond Shiels.

Rules under the Mental Treatment Act now in force will lapse on March 31st unless approved by both Houses. The sanction of the Commons was secured on March 16th, and was to be followed by an affirmative resolution in the Lords.

A meeting of the Parliamentary Medical Committee had been summoned for March 17th, but was postponed for a week.

Conversations upon the Pharmacy and Poisons Bill between the Government and professional interests were arranged for March 18th.

Poisons and Pharmacy Bill

Debate in the House of Lords

In the House of Lords, on March 12th, Lord PONSONBY moved the second reading of the Poisons and Pharmacy Bill. He said this was a Home Office Bill, and was the outcome of a report by a Departmental Committee which the last Government had set up to examine the law in regard to poisons. At present the substances and preparations treated as poisons for the purposes of the various Pharmacy Acts were scheduled as such by Order in Council upon the resolution of the Council of the Pharmaceutical Society. The retail trade in all poisons and preparations containing poison was reserved to registered pharmacists, except in the case of poisons required in agriculture and horticulture, which might be sold by persons licensed for the purpose by the local authority. The local authority was required, before granting such licence, to take into consideration whether in the neighbourhood the reasonable requirements of the public in respect of the purchase of the poisons in question were satisfied. The expression "reasonable requirements" had led to a good deal of dispute. In other sellings of poisons by retail the enforcement of the law lay with the Pharmaceutical Society, and the penalty which was obtained by a civil action was paid to the society. There was practically no regulation of the wholesale sale of poisons or the manufacture of medicinal preparations containing poison.

The Departmental Committee had found that the existing law in which the practice of pharmacy and the sale of poisons were mixed up was complicated, very largely obsolete, and not adapted to modern requirements. Some provisions were unnecessarily restricted, and in other respects the present control was far from adequate. Partly because the administration and enforcement of existing Acts lay with an unofficial society with insufficient resources, the law was not being enforced at present. The committee thought that a non-official body, whose members had a direct financial interest and which did not represent all the interests affected, was not the right body to regulate such matters. These matters, affecting the health and safety of the public, should be administered by a Minister responsible to Parliament. A long succession of cases of murder by poison and of accidental death by poison had shown the need of precision in the law with regard to poison and of greater care in enforcing it. There was also a demand from the agricultural community that the law should be altered so as to allow firms or co-operative societies which supplied the general needs of farmers and horticulturists to supply them with such substances also as sheep-dip and insecticides. The report on the subject had been made by a strong committee, including Sir Donald MacAlister, President of the General Medical Council, and Sir William Willcox, a prominent toxicologist. Their report was practically unanimous.

Provisions of the Bill

Lord Ponsonby then summarized the Bill, and explained that it transferred from the Pharmaceutical Society to the Home Secretary the duty of determining what were to be treated as poisons and of administering the law, including the making of regulations. The Home Secretary would be assisted by a Poisons Board, composed of technical experts, representatives of medicine, of pharmacy, and of Government Departments. The Bill provided for a new Poisons List in two parts—the first including those poisons which might only be sold retail by registered pharmacists, and the second for poisons which could also be sold retail by other persons or firms registered for the purpose with the local authority. The local authority could only refuse to register on the ground that the applicant himself was unfit or that the premises were unsuitable. This provision would meet the demands of the agricultural and horticultural community, and would remove hindrances now existing to the efficient supply of disinfectants. Poisons in Part 2 would in the main be sold in sealed containers and would bear appropriate warnings. They would be preparations in general use for sanitary, industrial, domestic, agricultural, or horticultural purposes, or as vermin killers. The sale of these would be controlled by regulations drawn up by the Poisons Board, and more effective than at present. An important new power was given to prohibit by regulation or by rule the sale, except on the prescription of a registered practitioner, of certain medicinal substances of a specially dangerous character. Examples of such substances were veronal and other drugs in the same group, which were much in vogue for inducing sleep. This reform had been frequently recommended by coroners. The Poisons Board would include a representative of the Home Office, another of the Scottish Office, two from the Ministry of Health, one from the Ministry of Agriculture, the Government chemist, five representatives of the Pharmaceutical Society, one from the Royal College of Physicians of London, one from the Royal College of Physicians of Edinburgh, and one from the General Medical Council. The Secretary of State, after consulting this Board, could draw up rules as to containers, labelling, transport, and storage; rules requiring the addition of some ingredient to make a poison readily distinguishable; and rules relating to the wholesale sale of poisons. Similar powers were given to the Pharmaceutical Society by the Act of 1868, and the Act of 1908 authorized regulations by Order in Council

for the sale of certain poisons. Rules would be laid before Parliament, and would be subject to annulment by Parliament. Lord Ponsonby pointed out that at present there was no legislative control over the manufacture of pharmaceutical preparations containing poisons, although it was increasingly the practice for such preparations to be compounded by a wholesaler, and not in the chemist's shop. The Bill enabled rules to be made requiring such preparations to be manufactured under the control of a registered pharmacist or other qualified chemist. The Bill and the rules under it would make it more difficult for persons to obtain poisons for criminal purposes without detection. Wholesale as well as retail dealers would be required to keep proper records, and would be subject to supervision. The Bill strengthened the representative character and disciplinary powers of the Pharmaceutical Society. It made every registered pharmacist a member of the society, leaving the Privy Council as central authority for the pharmaceutical profession as it was for medicine and dentistry. The Bill gave the Privy Council power to nominate three members of the council of the society. At present a pharmacist could not be removed from the register except on conviction for an offence against the Pharmacy Act. The Bill provided for a statutory committee which would have the power, subject to an appeal to the High Court, to remove from the register any pharmacist guilty of a criminal offence or of conduct which rendered him unfit to be on the register. At the same time the Bill recognized the right, which was denied by existing Acts, of a scientific chemist to use the title of chemist for purposes other than retail business. The Government had been in close touch with the Pharmaceutical Society in framing the Bill, and was ready to put down amendments on the committee stage to adjust points of detail which were still outstanding. He trusted that Lord Dawson, who had put down a motion for the rejection of the Bill, would also wait for adjustments at the committee stage and not persist in opposing the second reading.

Lord Dawson's Criticisms

Lord DAWSON OF PENN said the Bill had been drawn up without consultation with the medical profession, although medicines were prescribed by, and the handling of poisons mainly rested with, the members of that profession. On the Departmental Committee which investigated the subject there was only one practising physician. After that committee had reported, the Home Office failed to confer with the representatives of the medical profession, with the Royal Colleges, or with the British Medical Association. The staff of the Home Office included few medical men. The Home Office regarded drugs from the point of view of criminal intent and drug addiction, but in these aspects only a small fraction of the population were concerned. Drugs and poisons in day-to-day use were matters which concerned the general health of the nation, and drugs could not be separated from poisons. A large proportion of the drugs in use were potential poisons. Whether particular drugs should be put into the scheduled list could only be decided by those with specialized knowledge of clinical medicine, of pharmacy, and of chemistry. The work was done at present on the whole very well by the Pharmaceutical Society. That body could be made even better by adding to the skilled pharmacists one or two skilled chemists and a representative of practising physicians. The Advisory Committee to which the Bill proposed to transfer administration of poisons was a sham. The Home Secretary would appoint the chairman and four additional members, and would have power under another clause in the Bill to override advice and to act on his own terms. The real authority with regard to poisons would be transferred to permanent officials of the Home Office, who knew nothing about clinical medicine, and whose outlook would really be confined to people who were drug addicts, or had criminal intent. On the Poisons Board there would be three physicians out of eighteen members, and most of the members would have very little knowledge of the subject. It would be in the power of the Secretary of State to overrule the Board and to act as he pleased. The Board would be a bureaucratic body, and the proposal to establish it was a bad provision. Time after time measures were brought forward without proper consultation with the medical profession. There had been a great deal too much of this. Proceeding, Lord Dawson said that if those who knew something about pharmacy had been consulted the Bill would have been far better. With regard to poisons, he thought that the body proposed was of the wrong type. The proper principle was to delegate difficult technical questions to semi-autonomous bodies. That had been done in the case of radium. For these reasons he asked the Lords to reject the Bill, and added that he was not against the improvement of the profession of pharmacy. It was the policy of the medical profession to raise the status of these ancillary callings.

Lord ASKWITH said he endorsed the arguments of Lord Dawson and supported the rejection of the Bill unless the Government could show that the measure could be extended to meet the desires of the medical profession and the Pharmaceutical Society. He had been in consultation with the latter body. The Pharmaceutical Society had been established by a Royal Charter in 1843, and had controlled poisons since 1862. This Bill would take away a large portion of their power without altering their constitution as they desired or widening their sphere. The society pointed out that the Bill would not deal with such substances as vaccines, thyroid extract, and serums which grew old and stale and might become poisonous. There should also be elasticity to permit inclusion in the poisons list of new substances or substances which, in the future estimation of science, became poisonous. Under this Bill shops could be set up by anybody for the sale of substances which might be very deleterious. Any person could apply, and unless there was objection to his personality, or to his premises, a licence had to be granted him. That was much too wide. He thought that a committee on the Bill should also consider whether the Pharmaceutical Society should be widened into two grades, one of those who had passed difficult examinations and the other of those who were sufficiently skilled, under the supervision of a doctor or by their own knowledge, to dispense medicine.

The Earl of ONSLOW said that every reasonable step had been taken to obtain the advice of those who were competent to give it from the medical point of view. It was the universal practice that the Home Secretary, or a responsible Minister, should have the last word in such matters as those with which the Bill was concerned. He recommended the House to give the Bill a second reading and to endeavour to improve it in committee.

The Earl of HALSBURY said that since 1868 the whole practice of pharmaceutical chemistry had altered. New drugs were got out every week, and a board was required which could deal with them from a technical point of view, and put them on the danger list without consulting Whitehall and before any of the public got hurt by them. At present the Poisons Schedule contained the dangerous word "derivatives." For instance, it mentioned veronal and its derivatives. It was difficult to say that medinal was a derivative of veronal, and yet both were derivatives of the same original substance. The Bill should not be fought on party lines, as all desired an amelioration of the present law, and he hoped the House would not divide. Viscount LEVERHULME agreed that legislation ought to be carried to ensure that prescriptions were made up by a qualified pharmacist. He supported Lord Dawson's protest against the failure to consult the medical profession sufficiently regarding this Bill. Lord COZENS-HARDY also strongly supported Lord Dawson.

Government's Reply

Lord PONSONBY, replying to the debate, said that the Government intended taking into account all bodies which were closely connected with the question of the control of poisons. In reply to Lord Dawson's complaint, he said that Sir Donald MacAlister, a very high medical authority, had been on the committee of inquiry. That committee's report had been published for a year, and the Government would have been glad to have had consultation with high medical authorities. Lord Askwith had raised the question of extending the Bill to such things as vaccines, serums, and thyroid extracts. No inquiry had been instituted into this branch of the subject, and the Government felt it was inadvisable to go beyond the actual question of poisons. That was the only point on which the Government could not accept any amendment of the Bill. On the committee stage they were ready to consider alterations of the constitution of the Poisons Board. The opinion of Lord Dawson carried so much weight that the Government could not go forward while he was in opposition. Lord Ponsonby offered to postpone the committee stage, and suggested that before then the Registrar of the Royal College

of Physicians should get together a representative body to consult with the Home Office on the Bill. Unless the Bill could be sent to the House of Commons before Easter its chances of passing into law this session would be remote. Answering Lord Phillimore, Lord Ponsonby said the Government was not opposed to the extension of the Poisons List. The Pharmaceutical Society had desired to extend this Bill to the dispensing of medicines that did not contain poisons, and although there might be need for review of the Pharmacy Acts this Bill was intended to deal exclusively with poisons.

Lord DAWSON withdrew his motion for the rejection of the Bill, but expressed a doubt whether it would be possible to get together within a fortnight the medical experts with whom the Government had suggested a conference. Lord PONSONBY said that in any case the Government would have to proceed with the Bill on March 26th.

The Bill was then read a second time without a division and remitted to a committee of the whole House.

The Army Estimates

In the House of Commons, on March 10th, Mr. SHAW moved that the House should go into committee on the Army Estimates. He said that there was a net saving on the year of £570,000, the largest item of which was in respect of the fall in the cost of living. Between October, 1929, and the end of September, 1930, 66,717 men had offered themselves for the Army. Some 52 per cent. of these men could not be accepted owing to their poor physical condition. Serious diseases which used to be prevalent in the Army had diminished to a marked degree. Interest had been aroused in the House in regard to Porton, an establishment for studying the best methods of defence against poison gas. In regard to the experiments on animals carried out at Porton he assured the House that it was quite untrue that torture in the sense of violent pain was being wantonly inflicted. The question which he had to answer, as one responsible for ministerial policy, was: "If it is demonstrated to you that by an experiment on an animal you might be able to devise the means of saving an enormous amount of human suffering, are you prepared to face the experiment?" To that question his answer was, "Yes." He was satisfied that everything possible was being done to avoid suffering, and that when any animal showed signs of great pain it was at once painlessly destroyed. This was a service which was common to the Navy and the Air Force, as well as to the Army, but he took full responsibility, as Minister of War, for its continuation. He would do his best to see that it was conducted in future on the same lines. Major TRYON said that, since they tried to enlist the healthiest people in the country, it would be a great pity if those recruits were not provided with the best medical attention while they were in the Army. There was at present a great shortage of medical officers, and he was glad that the Secretary for War viewed the position with concern.

Mr. HASTINGS said that there were two reasons for the falling off of professional interest in the Army Medical Corps. One was that the Army now provided a very healthy life, and the other was that the remuneration was small. Owing to the panel service, a doctor, by putting up a brass plate in an industrial area, could, in a year or two, make a better salary than he could obtain in the Army. The solution of the difficulty could only be found in the amalgamation into one comprehensive body of the medical services of the three fighting forces with, possibly, the medical services of other State departments.

Mr. MACPHERSON remarked that it was a sad comment on present-day recruiting that 52 per cent. of the recruits who offered themselves belonged to a C 3 population. It might be that the slum conditions prevailing in some barracks were to some extent responsible for the outbreak of spotted fever at Aldershot. The present state of the Royal Army Medical Corps was extraordinary. There was no longer any competition to enter the Service. He was told that, out of 600 officers, 500 were majors and 100 were subalterns, and the majors had to do mostly subalterns' work. If the health of the Army was to be properly looked after they could not have a disjointed and chaotic corps of that kind. At present there was no chance of promotion; the pensions and allowances were miserable, and no special grants were made for specialist services. Mr. SANDERS, Financial Secretary to the War Office, said that the number of medical officers in the Army fell short of establishment—namely, 823—by 173. The foreign establishment was kept up, so also was the Indian. The problem affected not only the War Office, but the Admiralty and the Air Ministry. An interdepartmental committee was being set up by the three Services with the object of finding some solution. His own view was that the problem was mainly a financial one. If the rates of pay of the Army Medical Corps were increased, would not other corps and departments and classes in the Army also demand that they should be put on the same level? Were doctors to have special privileges? All those matters would have to be considered in the light of the needs of the three Services. He was informed that there were 107 members of the R.A.M.C. who had specialist pay of 5s. per day extra.

Dr. FREMANTLE said the position now was that medical officers going overseas came back after five years' service and, after having only one or two years at home, had to be detailed for another five years' foreign service. When young officers, especially those who were married, had been sent back for a second term they said that they could not take it any longer. They could not stand constant terms of foreign service. Therefore it was with the greatest difficulty that the War Office could fill the foreign service roster this year. He gathered that it was most unlikely that next year it would be able to fill the roster. He understood that those who had been investigating this matter sympathetically—the British Medical Association Committee concerned—estimated that there would be another two hundred resignations within the next two or three years, and the Service would be cut down to one-half. It was impossible to fall back on the members of the civilian medical profession, who were not anxious to go abroad for any length of time with military expeditions. He remembered the scandals at the beginning of the South African war, which he witnessed as a young civil surgeon in South Africa. All the force and fury of public opinion were brought to bear against the War Office for not having made proper provision. Inside the War Office the full blast fell on the Surgeon General of the Army Medical Service, who had been making constant representations in regard to the inadequacy of the provision made for him; the position was exactly the same to-day. Ever since the war the same representations had been made by successive Directors-General of the Medical Service to every Secretary of State in each Government. In each case they had been told that they were asking too much, or that it did not matter very much, as the young men could always be obtained. Other officers in the Army said, "Why should these people be paid so much better than we are?" Their market value was different, because the young medical student had to give up six or seven of the best years of his life to a profession which was so grinding that it prevented three-quarters of the men who entered it from getting to the end. If, at the end of that period, a student managed to get equipped, he was going to see that he got the best terms for the rest of his life, and small blame to him. When he was asked to join the medical services of the three Forces he saw, first of all, that he had to be disciplined, and there was nothing a medical man disliked more. The Army offered him a position in which he was at once jockeyed out abroad, and, if he happened to come home for a year or two years' service after two or three years abroad, out he went again for another five years. The Army did not offer him a career. Lieutenant-colonels and majors retired from the medical service at 45 on a bare pound a day; that fact was a standing advertisement not to join the Army. The young medical man did not want to be unoccupied at 45, and turned loose to the end of his life. The three Services between them were appointing an interdepartmental committee to consider this question. The Warren-Fisher Committee undertook the same work in 1925, and came forward with proposals which, at the time, seemed to do what was required. This was a repetition of the same process. They would have to look further to give a career to these young men if they were to keep them. That career must be something much more than anything that could be offered by the Army alone. There was also the possibility of combining the three fighting Services. Recent reforms had had the disastrous effect of destroying the most magnificent medical service the world had ever seen—the Indian Medical Service—which was sacrificed on the altar of

Indian nationalism. His friends had looked forward to combining the Indian Medical Service with the medical services of the Army, Air Force, and Navy. That could not be done but the Colonial Medical Service might possibly be carried on. He believed that two thousand young men had enlisted in that Service since the war. The State should be master in its own house, and he could not see why there should not be one comprehensive service. They must first deal with the repeated foreign tours of service for men who joined. Young medical men might be induced to undertake five years' commission, with a term of foreign service, if given satisfactory conditions, especially a good gratuity at the end to help them to settle down in private practice. The State contributed very largely to the employment of medical officers of health engaged in local Government services, and it was possible to envisage some wider field of employment with a common entry and with ultimate employment in the Civil Service as well as in those Services which took them overseas.

Mr. SHAW said that the supply of medical men was one of the most difficult problems which the Ministers for the Defence Forces had to face, and no Department alone could solve the difficulty. He assured Dr. Fremantle that the closest attention would be given to his statement that the terms of foreign service discouraged medical men from joining the Army. The War Office would do what was best in the circumstances. In his opinion the question was still largely one of money, but if they had all the wealth they desired and gave it to the medical service, dissatisfaction would be created in other Arms of the Service and the Government would be at the beginning of its troubles. The three Services would consider the problem together and endeavour to find a way out. He frankly admitted that the difficulty ought not to exist for a moment longer than was necessary.

The House then agreed to the Army Estimate for men.

B.C.G.

On March 10th Mr. GREENWOOD told Mr. Bromley that he had no information as to the distribution of Calmette vaccine to medical practitioners in this country, and he would be obliged for any particulars that the honourable member could give him. It was not considered that the deaths at Lubeck were traceable to the original B.C.G. cultures; and, as particulars of these deaths and reports on the subsequent inquiries, and upon the use of B.C.G. generally, had appeared in the medical press, no further action was necessary to bring the matter to the notice of members of the medical profession in this country.

R.A.F.M.S.

In answer to Dr. Fremantle, Mr. MONTAGUE circulated the following table on March 13th:

Medical Officers, Royal Air Force

Year	Establishment	Deficiency	Year	Establishment	Deficiency
1920 ..	142		1926 ...	210	51
1921 ..	141	29	1927 ...	204	40
1922 ..	177	50	1928 ...	204	26
1923 ..	197	55	1929 ...	205	28
1924 ..	213	65	1930 ...	210	39
1925 ..	219	68	1931 ...	210	46
		70			

In a footnote Mr. Montague added that these deficiencies of regular officers have been made good to a substantial degree by the engagement of doctors on contract, either on a commissioned or on a civilian basis.

Cancer Statistics

Mr. GREENWOOD told Mr. Freeman, on March 12th, that the provisional figure for deaths registered during 1930 in England and Wales classified to cancer was 57,870. No information was available with regard to how many of these persons were habitual consumers of flesh foods, beer or spirits, or non-flesh diet. Registrars of births and deaths were not entitled to obtain any information with respect to a death other than that relating to the particulars required by law to be registered, and it would not be possible to adopt the suggestion that registrars should furnish information regarding such matters of diet.

Replying on March 12th to the Countess of Iveagh, Mr. GREENWOOD said he had no more recent information than that contained in the Report of Public Health of 1927 with regard to the mortality following on Wertheim's operation for the treatment of cancer of the cervix uteri. The determination of the results of radiological treatment of uterine cancer, and their comparison with the results of surgical operations, were receiving continued attention, not only from the Health Committee on Cancer, but also from the health organization of the League of Nations, which had arranged for the collection of international data on the subject. He was, however, advised that, in the nature of the case, it was not yet possible to make or publish effective comparison of the risks or results of these methods of treatment.

Milk Supply

Mr. GREENWOOD told Mr. Longbottom, on March 12th, that he had received from several county boroughs a resolution requesting that, owing to the high incidence of tuberculosis among dairy cattle, he would amend the Milk and Dairies Acts of 1915 and 1926 so as to confer on local authorities the power to make compulsory the notification of all cattle arriving in their respective areas within forty-eight hours of arrival. He would consider this resolution in consultation with the Minister of Agriculture.

Replying to General Clifton Brown on March 12th, Mr. GREENWOOD said he would consider the suggestion that a study be made of the relative nutritional values of the different types of milk which are on sale, either by the Medical Research Council or by the committee which the Government had recently set up to study the nutrition of the nation; also that the research experiments of the Dairy Research Institute at Shinfield in that direction should be carefully considered.

National Health Insurance

Mr. GREENWOOD told Sir Kingsley Wood, on March 12th, that two important changes in the Medical Benefit Regulations had been made to protect the National Health Insurance funds against abuse. The first referred to the transfer of insured persons from one doctor to another, and the second to lax certification. He also proposed to issue at an early date to all insurance doctors a memorandum, and to all approved societies a circular, giving the results of recent investigations into the increase of sickness and disablement benefit claims and advice on medical certification and the supervision of claims.

Food Preservatives.—Replying to Colonel Ruggles-Brise on March 12th, Mr. GREENWOOD said that nearly all chemical preservatives were injurious or objectionable in some degree, but sulphur dioxide and its compounds—the preservatives used in fruit and fruit pulp—were among the least objectionable. It was necessary on practical grounds to tolerate the use of these preservatives to a limited extent. The regulations applied to imported and home-produced fruit were substantially in accordance with the recommendations of the Departmental Committee on Preservatives in Food, 1924.

Maternal Mortality.—Mr. GREENWOOD told Mr. Leach, on March 12th, that the selection of the deaths for inclusion in the maternal mortality rates published by the Registrar-General was governed by the medical certificate that death was directly or indirectly due to certain causes, and did not depend upon the time which elapsed between the confinement and the death.

Radium.—Mr. GREENWOOD told the Countess of Iveagh, on March 12th, that he understood arrangements had been made by the Radium Commission to obtain annual returns showing results from the radium centres to which radium was lent by the Commission. He would consider obtaining similar returns from local authorities in whose institutions radium was used.

Asylum Officers' Superannuation.—It is hoped to complete in two or three weeks the collection and tabulation of statistical matter with regard to the actuarial position under the Asylum Officers' Superannuation Act, 1909. The Government actuary will then be able to prepare a report.

Medical News

A Chadwick public lecture will be given by Professor Major Greenwood, on nerves and the public health, at the British Medical Association House, Tavistock Square, W.C.1, on Thursday, March 26th. Sir James Purves-Stewart will take the chair at 5 p.m.

The annual meeting of the Mental After-Care Association will be held at the Haberdashers' Hall, Gresham Street, E.C., on Wednesday, March 25th. The chair will be taken by Lord Wakefield of Hythe at 3 p.m.

A meeting of the Medico-Legal Society will be held at 11, Chandos Street, W.1, on Thursday, March 26th, at 8.30 p.m. Mr. F. L. Collins, F.I.A., will read a paper entitled "Mortality tables, their history, construction, and use," which will be followed by a discussion.

The next meeting of the Optical Society will take place at the Imperial College of Science and Technology, Imperial Institute Road, South Kensington, S.W.7, on March 26th, at 5.30 p.m. The attention of members is directed to the altered time of this meeting.

The annual general meeting of the Cremation Society will be held at 23, Nottingham Place, W.1, on Wednesday, March 25th, at 3.30 p.m.

A reception will be held on Tuesday, March 24th, at Queen Charlotte's Isolation Hospital, Ravenscourt Square, Hammersmith, W., to view the new hospital and research laboratories. Dr. Leonard Colebrook, director of research, will speak, at 3.15 o'clock, on the puerperal fever research to be undertaken in these laboratories.

The next reception of the Royal Society of Medicine will be held at 1, Wimpole Street, W.1, on Monday, April 20th, at 8.30 p.m., when the President and Mrs. Watts Eden will receive Fellows and their friends in the library. At 9.15 p.m. an illustrated address, entitled "*Some aspects* of Alpine climbing," will be given by Dr. Claude Wilson, president of the Alpine Club. Various objects of interest will be exhibited in the library. Admission will be by ticket only, application for which should be addressed to the secretary.

Dr. Maurice A. Bigelow, professor of biology at Columbia University and chairman of the executive committee of the American Social Hygiene Association, will deliver a lecture entitled "Social hygiene and the family" at the Marble Arch Rooms, Old Quebec Street, W., on Tuesday, April 21st. The Duchess of Atholl, M.P., will preside. Admission free by ticket, which can be obtained from the secretary, British Social Hygiene Council, Carteret House, Carteret Street, S.W.1.

The annual meeting of the Society for the Study of Inebriety (Alcoholism and Drug Addiction) will be held at the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, W., on Tuesday, April 14th, at 4 p.m. After the transaction of business, Dr. Charles W. J. Brasher, medical superintendent, Woodlands Park, will read a paper entitled "Absinthe addiction and the cocktails habit."

Particulars of the lectures and demonstrations arranged for next week by the Fellowship of Medicine will be found in our Diary of Post-Graduate Courses, published in the *Supplement* at page 96. Several special courses have been arranged to be held under the auspices of the Fellowship after Easter. Copies of syllabuses and tickets of admission can be obtained from the Fellowship, 1, Wimpole Street, W.1.

A course of nine lectures and demonstrations in tropical hygiene and nursing arranged by the County of London Branch of the British Red Cross Society will be given on Monday, Wednesday, and Friday evenings, at 9, Chesham Street, S.W.1, commencing on Friday, April 10th, at 5.30 p.m. An examination for the society's certificate in tropical hygiene will be held on May 1st. The fee for the course to members of the Red Cross and voluntary aid detachments is 5s., and for non-members 7s. 6d.

A course on post-graduate study on radium, pneumothorax and haematology will be held at the Aberdeen Royal Infirmary and Aberdeen University on Tuesdays and Thursdays at 3.15 p.m., from April 21st to June 2. A syllabus of the lectures and demonstrations may be obtained on application to the secretary, University, Aberdeen.

An examination for the Chesterfield medal, which is open to all qualified practitioners, will be held at St. John's Hospital for Diseases of the Skin, Leicester Square, W.C.2, on March 30th and 31st at 10 a.m. Full particulars can be obtained on application to the dean.

A summary of Mr. Justice McCardie's Maudsley Lecture, entitled "Truth," appeared in our issue of November 29th, 1930 (p. 921). The full text has now been published, on behalf of the Royal Medico-Psychological Association, by Adlard and Son, Ltd. (21 Hart Street, W.C.1), at the price of 4d.

Of the eighty-eight Italian graduates on the *Medical Register* for 1930, not more than a dozen are practising in Great Britain, a small number live in Italy, and the majority are settled in the Colonies and Dominions.

The three psychiatric societies of Paris—namely, the Société Médico-psychologique, Société Clinique de Médecine Mentale, and Société de Psychiatrie—have recently been merged into one, with the *Annales Médico-psychologiques* as the official organ. Dr. R. Charpentier is permanent secretary.

Professor K. F. Wenckebach of Vienna has been invited by the Queen Wilhelmina Jubilee Foundation to investigate the pathology of the heart in acute beri-beri at the recently established medical faculty at Batavia in Java.

In Paris an institute of physico-chemical biology has been founded by Dr. Edmond de Rothschild.

Dr. G. Lemoine of Lille has been elected president of the professional association of French medical journalists.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the British Medical Journal must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecta Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: Bacillus, Dublin; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: Associate, Edinburgh; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Sensitiveness to Sunshine

"A. S. P." (Liverpool) writes: I have a patient, aged 54 years, who is quite unable to allow the sun to shine upon her. An exposure of five to ten minutes brings out an intense irritation of the part exposed, and an erythema. Her movements in the summer are very much curtailed in consequence, and I should welcome any advice by which I could help her.

Mammary Abscess

...rites: In reply to "Suburban G.P." (March 14th, "... the probable causation of these cases is as follows. ...s of all classes seem firmly to believe that they ...moisten the nipple with saliva before putting it in the ...s mouth. The probable sequence of events is dental ...s, unwashed nipples, cracked nipples, mammary ...cess. Few mothers take the trouble to wash and dry ... nipple after nursing; a mere wipe is not enough. Very ...ten the left breast is used more than the right; it is ...sually the first one given when both are used at a feed, ...and it is often given alone. I do not consider spirit or any hardening agent necessary for the nipples, but careful cleansing most certainly is essential.

Paroxysmal Rhinorrhoea

Dr. J. FULTON CHRISTIE (Glasgow) writes in reply to "Ninety-nine" (March 7th, p. 432): The history is that of a typical case of paroxysmal rhinorrhoea or vasomotor rhinitis. Recently I have been treating a series of patients suffering from this condition with parathyroid extract 1/10 grain and calcium lactate 15 grains twice daily, over a period of six weeks. This treatment has been described before, and is not original. The results which I have been getting have been good, a definite improvement being obtained in almost every case. It is essential that septic tonsils or sinus disease, when present, should be first dealt with. The doses stated are for an adult.

A Headache Powder

"W. F." was called to see an adult male patient who was in great distress. Five hours earlier he had taken a "head and nerve powder" for a headache and gone to lie down in bed. An hour later he began to feel queer, and when his wife saw him she became alarmed at his appearance. Our correspondent saw the patient five hours after taking the powder. His eyes were then puffed and almost closed, and his face was greatly swollen. He said his head felt as if it were going to burst, and he was weak all over. The pulse rate was 96. The symptoms soon subsided.

*** The sample powder forwarded by "W. F." has been examined on our behalf, and was found to contain acetanilide and tartaric acid, approximately 8 grains of the former and 2 grains of the latter in the 10-grain powder. The Pharmacopoeial dose of acetanilide is 2 to 5 grains.

Miscarriage of One Twin

We have received the following from Dr. H. COHEN (Cardiff): Dr. Boyd Roberts's note in the *Journal* of March 14th (p. 479) recalls to my mind that just over two years ago I attended a primipara in her confinement, which was a fairly easy forceps case, followed by a perfectly normal third stage. The puerperium was uneventful, till on the fifth day she passed what strongly resembled a carneous mole. This was preceded by some uterine pain, but little or no haemorrhage. The temperature and general condition remained undisturbed, and the patient's progress was uninterrupted. As the expelled tissue was certainly not placenta or recent blood clot, I could only explain what happened by supposing that she had had a twin conception, and that one foetus had "missed fire," resulting in a blood mole, which was retained and not cast off till after labour took place. I may add that six months ago the patient had a second baby, both the confinement and puerperium being normal.

LETTERS, NOTES, ETC.

Diverticula of the Duodenum.

Dr. JULES REY (Bognor) writes: I add two more cases to the list for those who are interested in this condition. (1) A woman, aged 42, who was labelled a "neurotic" and "hysterical" derelict, drifted into my hands and, among other investigations and tests, I gave her a barium meal. The startling discovery was made that she had a diverticulum about 3 to 4 cm. in diameter, almost globular, and situated in the third part of the duodenum or first part of the jejunum. Unfortunately, owing to the exigencies of my practice, I could not spare the time to photograph the condition. It could easily be emptied by deep massage in the middle line of the body. She fully recovered her former good health, due almost entirely to the frequent evacuation of the contents of this diverticulum by manual pressure. Five years have elapsed, and still, with careful dieting, she remains in very good health. (2) A married man came to me on March 11th, complaining of dull constant epigastric pain. Appendicectomy had been done in December, 1930, with no relief. By *x*-ray examination a hypertonic stomach was found, there being also increased peristalsis, an irregular duodenal cap, and duodenal ileus. Nine hours after ingestion, when the stomach was nearly empty, except for a faint crescent of the greater curvature, a very small diverticulum was seen at the junction of the first and second part of the duodenum, a respiratory excursion of 5 to 8 cm. taking place. Several hours later the diverticulum had completely disappeared. It will be interesting to note if all his symptoms disappear with careful dieting and the administration of alkalis.

Treatment of Obesity in a Multipara

"M.B., B.S." writes: Perhaps my personal experience may be of some help. After the birth of my second child I began to put on weight rapidly. From my normal weight of 11 st. 7 lb. I went up to nearly 14 st. I began to take Burroughs Wellcome's thyroid extract (fresh gland), beginning with doses of half a grain three times a day. I pushed this gradually until I noticed signs of hyperthyroidism. This occurred when I was taking 20 grains a day. I reduced the dose to 15 grains a day, and I have gradually lost weight, and am now back to 11½ st. People remark on my slimness and youthful look. I am 38 years of age and 5 ft. 9 in. in height. I am now taking 15 grains every other day with my early morning tea. The slimming process I have described took eighteen months. The only drawback to this dosage that I have noticed is a feeling of tiredness towards the evening. I have had the same result in a patient who got suddenly fat after a confinement; but she needed only five grains a day to reduce her to normal.

Treatment of Cancer of the Bladder

Dr. W. M. CORBET (London, E.C.) writes: The article just published under the above heading will further trouble the muddy waters for the average practitioner. To the urologist the position is crystal clear, and reduces itself to the indication for immediate cystoscopy at the onset of any urinary haemorrhage. A cancer of the bladder is never fulminating *ab initio*, like, for example, a melanotic sarcoma. Practical experience in cystoscopy teaches one that these growths almost always commence as benign papillomata, responding readily to trans-urethral diathermy with a sufficiently powerful current and a sufficiently heavy electrode. They only gradually take on malignant characteristics; and the vesical neoplasm which, when seen for the first time, whether by abdominal section or cystoscopically, is undoubtedly malignant, is a growth seen too late—as much so as if it were situated in the breast or the lip. The obtaining of a proper specimen for microscopical examination is usually not a practical proposition. The writer, while stressing the difficulty of exact diagnosis of the stage of malignancy, lays down excision as the method of choice. I think most urologists would agree with me in placing excision third on the list, and advising, first, cystoscopic diathermy—under sacral anaesthesia if need be—and, secondly, open diathermy. Radium, in my experience, is a lamentable failure in this region, only prolonging the agony. The quoted statistical mortality of 75 per cent. in vesical cancer is surely the strongest plea for the early cystoscopic exploration I urge.

Analgesia in Childbirth.

Dr. A. Z. C. CRESSY (Wallington) writes: In a letter published in the *British Medical Journal* of October 25th, 1930, I referred to ovarian residue in labour, and I have since had letters on the subject from doctors in China, America, Africa, Ireland, Scotland, and several in England, all asking for details. This shows that the general practitioner is on the look out for anything that may improve his practice, and that he does take an interest in midwifery.

Corrigendum

We regret that in Mr. Holt Diggle's paper entitled "Intranasal dacryocystostomy for relief of lacrymal obstruction," published in our issue of March 7th (p. 391), the word "apart" was erroneously inserted in the following sentence: "Other factors . . . no doubt prejudiced a favourable result in what was *apart* from the consistency of the sac an easy operation."

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 53, 54, 55, 56, 57, 60, and 61 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 58 and 59.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 95.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

263 Myocardial Diseases

H. L. HEIMANN (*Journ. Med. Assoc. of South Africa*, January 10th, 1931, p. 8) remarks that estimation of the myocardial integrity is difficult when obvious defects such as valvular disease are absent. All valvular lesions except the congenital forms are associated with myocardial defect, but the onset is obscure and the symptoms are indefinite. The recognized terminations of myocardial disease are (1) congestive failure, (2) angina, (3) coronary thrombosis, (4) the Stokes-Adams syndrome, (5) ventricular fibrillation, and (6) myocardial rupture; two or more of these may be associated. Ventricular fibrillation and ventricular rupture are most rapidly fatal, and congestive failure is the slowest. Chloroform anaesthesia may produce fatal ventricular fibrillation in a healthy myocardium; as a terminal phenomenon fibrillation connotes a final effort of dying muscle. Rupture is rare, but it may result from an infarction or from fibrosis due to a gumma. The Stokes-Adams syndrome may terminate in death during asystole. Congestive failure commences clinically with dyspnoea, but this is not pathognomonic. Cyanosis may occur, and a history of rheumatism or syphilis may assist diagnosis. Rheumatic myocarditis is associated generally with valvular lesions, usually mitral stenosis; it is seldom cured. Acute congestive failure, due to a transient condition such as severe tachycardia—for example, in sea-sickness—may subside completely, or remissions may occur. Congestive failure may be due to hyperpiesia, chronic nephritis, cardio-vascular syphilis, or acute infective carditis. Acute failure may ensue in the exanthemata. Angina may be fatal in a case which has shown no previous physical signs or symptoms. The quality of the heart sounds is often misleading in the diagnosis of myocardial degeneration, but the "gallop-rhythm" and "tick-tack" sounds are more reliable. The first always indicates myocardial breakdown, and is often accompanied by pulsus alternans. Exercise tolerance tests are of little value in prognosis, except when angina supervenes. Permanent hyperpiesia and a fall in blood pressure after exercise are important signs of severe myocardial inefficiency. Myocardial degeneration may develop in prostatic hypertrophy, and in toxic conditions such as exophthalmic goitre. Treatment of the thyrotoxic condition diminishes the myocardial lesion. Dysenteric paroxysmal tachycardia is of toxic origin.

264 Asymptomatic Neurosyphilis

J. E. MOORE and H. H. HOPKINS (*Journ. Amer. Med. Assoc.*, November 29th, 1930, p. 1637) present data from 123 cases, observed for an average period of seven years, of asymptomatic neurosyphilis; 55 were of the early and 68 of the late type. The patients were classified in three groups, according to the degree of the spinal fluid changes. The presence of a Group 3 fluid (maximal changes of the paretic formula) is strongly presumptive of a liability to the development of parenchymatous neurosyphilis. Eleven of the patients had died at the time of reporting, 5 from neurosyphilis. As the observation period was short, 38 questionable cases are noted by the authors as being likely to develop further. Spontaneous regression to the normal of positive spinal fluids is held to be rare. The authors believe that the presence of a positive fluid in patients with early or late syphilis is of grave prognosis, even though they present no objective neurological abnormalities; the ultimate danger to the patient is roughly proportional to the intensity of the spinal fluid changes. A negative fluid is, subject to certain qualifications, a practical degree of safety as regards the subsequent development of neurosyphilis. From these facts it is concluded that a routine spinal puncture is indispensable in every syphilitic subject.

265 Sex and Age Incidence in Asthma

K. H. BAAGÖE (*Ugeskrift for Laeger*, January 22nd, 1931, p. 79) has investigated 311 cases of asthma; 110 of these were in-patient hospital cases, and the remainder out-patients. There were 175 males to 136 females, and the excess of the former over the latter was most marked among the patients whose asthma had begun within the first five years of life (90 males to 60 females). This fact coincides with the observation that the general morbidity is higher among boys than girls in the first years of life. The sex incidence showed no difference in the case of patients whose asthma had begun between the ages of 5 and 40 (68 males to 69 females), but after this age the ratio of males to females was as 17 to 7. Among 155 asthmatic children 15 years old or younger, there were as many as 120 whose asthma had begun before they were 5 years old; but among 138 asthmatics over the age of 20, the age at onset of the first symptoms was fairly evenly distributed over the years of childhood and adult life. There would thus seem not to be any special age, as far as these 138 patients were concerned, at which persons are specially liable to develop asthma. In 293 cases the cutaneous reactions to 25 different substances were studied, and a positive reaction was obtained to feathers in 44 per cent.; to horse scurf in 10 per cent.; to cats' hairs in 9 per cent.; to cows' hairs in 8 per cent.; to dogs' hairs in 5 per cent.; to crayfish in 10 per cent.; to eggs in 2 per cent.; to fish in 2 per cent.; to lactalbumin in 2 per cent.; and to pollen in 15 per cent. Positive reactions to egg and fish were obtained only in children. While Walker found that 80 to 90 per cent. of his patients whose asthma had appeared in earliest childhood gave a positive reaction, and that the percentage of positive reactions declined as the age of onset rose, Baagöe found a positive reaction in 59 per cent. of his patients whose asthma had begun before the age of 5, and in 74 per cent. of those whose asthma had begun between the ages of 5 and 10. While only 42 per cent. of the females gave a positive reaction, 67 per cent. of the males did so.

266 Pseudo-tuberculous Measles Pneumonia

W. MIKULOWSKI (*Arch. de Méd. des Enf.*, December, 1930, p. 811), who records four illustrative cases in children aged from 2 to 4 years, states that owing to the close clinical and epidemiological connexion between measles and whooping-cough the most frequent complication of measles in young children is the so-called pertussis pneumonia, which often has a protracted course. This affection may be accompanied by dilatation of the bronchi and involvement of the pleurae with aseptic or microbial effusion of a serous, fibrinous, or purulent character closely simulating pulmonary tuberculosis. The opinion generally held regarding the reactivation of tuberculosis as the result of measles is mainly based on the clinical resemblance of pertussis pneumonia to tuberculous pneumonia. In view, however, of the inadequacy of the clinical methods of investigation, a diagnosis of tuberculosis can only be justified by a positive biological test or direct bacteriological examination of the patient's excretions or secretions.

267 Sublingual Mumps with Oedema of Tongue

E. H. R. HARRIS and E. C. BENN (*Brit. Journ. Child. Dis.*, October–December, 1930, p. 293), who record two personal cases, state that while sublingual mumps, either alone or in association with parotitis, is well known, and the occurrence in mumps of oedema of the neighbouring tissues, especially the larynx, is also well recognized, no previous cases have been recorded of oedema of the tongue secondary to sublingual mumps. Their first patient was a boy, aged 8, who was sent to hospital as a case of diphtheria. There was no clinical or bacteriological evidence of that disease, but the tongue was greatly swollen and protruded, the floor of the mouth was

oedematous, and the sublingual salivary glands were swollen and tender. The parotid and submaxillary glands were not affected. During the first few days the tongue was frequently swabbed with ice-cold water and the child was fed by nasal tube. Recovery without metastasis ensued in about seventeen days from the onset. No history of exposure to mumps was obtained, but the disease was prevalent in the town at the time. The second patient was a girl, aged 13, admitted to hospital with scarlet fever; she had been exposed to mumps a fortnight before admission. Four days later her tongue became swollen, and the sublingual glands were congested and tender. The submaxillary and parotid glands were not affected. Uncomplicated recovery followed in a few days.

268 Tularaemia in Norway

H. A. SALVESEN (*Norsk Mag. f. Laegevid.*, January, 1931, p. 28) records four cases of tularaemia, two of which belonged to the ulcero-glandular and two to the glandular type. All the patients had contracted the disease from handling hares. As far as could be ascertained the incubation period was from three to four days in each case. In one instance stomatitis developed during the disease. T. TIJÖTTA (ibid., p. 32) states that about fifty cases of tularaemia are known to have occurred in Norway, and that the number is steadily increasing. All forms of the disease have been encountered except the typhoid type. The disease has been met with in almost epidemic form in the ranches for fur foxes where the ranchers feed their animals with game, especially hares. In one case a man was infected by picking up a dead hare and looking at it, but without opening it; in another case the patient had merely carried a skinned hare wrapped up in paper. In the following instances infection through hares could be excluded—namely, two cases of the ulcero-glandular type that seemed to have been infected through the soiling of hands by the faeces of lemmings, two cases in field labourers harvesting crops in fields infested by the faeces of lemmings and field mice, one case due to the bite of a cat in a district where an abundance of dead field mice was found, one case following a fall on the ground with slight injury to the fingers, and, lastly, one case in which no explanation was forthcoming. These facts show that small rodents besides the hare—namely, lemmings and field mice—may become infected with tularaemia. Special interest attaches to the migrations of lemmings, millions of which stream in herds from the mountains to the valleys, and thus form a natural concentration of the virus of tularaemia. It had previously been noted by hunters and woodsmen that the years of lemming migrations were always followed by years in which there was a heavy mortality among hares.

269 Colonic Stasis of Hepatic Causation

E. ZEBROWSKI and E. BRATKOWSKI (*Rinascenza Med.*, January 1st, 1931, p. 5) describe a new syndrome which they call "hepatic tiflostasis"; they think it is not uncommon, since they have observed it 150 times in one year. The clinical symptoms include enlargement and distension of the abdomen associated with constipation. In almost half the cases of enlarged liver the authors detected an oval hard mobile mass, or a large broad rather soft mass occupying the whole iliac fossa. Radiograms eliminated other possible conditions, and showed that the enlarged liver in some cases was pressing on the colon, whilst in others it covered the hepatic flexure of the colon. The weight of the liver decreased the motility of the caecum; two forms of stasis are described—namely, the hypertonic (in youths) and the atonic (in old age). The syndrome is generally chronic. The acute form occurs in persons who have swallowed too much liquid or a large quantity of fruit together with kernels; it resembles appendicitis, but is distinguished from it by the enlarged liver, the vague pain, and the severe toxaemia. Treatment consists in lavage of the caecum, which in chronic cases is preceded by the administration of purgatives, and followed by the adoption of a vegetarian diet and by diathermy. Treatment is also required for the liver condition.

Surgery

270 Epidermoid Carcinoma in Sebaceous Cysts

E. L. BISHOP (*Annals of Surgery*, January, 1931, p. 109) asserts that the common sebaceous cyst or "wen" does, in a number of cases, develop into a malignant tumour. The formation of the cyst is due to mechanical blocking of the duct, followed by retention of secretion and accompanied by a continued and increased activity of the cells within the cyst. If infection, either acute or chronic, is added, there exists a suitable condition for the development of a malignant tumour. In certain cases, after the removal of a cyst, a recurrence in or near the scar may develop which is sometimes proved to be a carcinoma. Laboratory examination showed that out of 119 cysts and keratomas examined, eleven revealed definite carcinoma, two others such marked epithelial activity as to be classed as precancerous, and one case was known to be malignant. The tendency towards malignancy increases with the age of the patient; the average age for benign cysts was found to be 38, whilst in the eleven cases of carcinoma the average age was 64. The proportion of carcinoma in cysts was much greater in the female than the male, being in the ratio of 8 to 3. The scalp and face are the most common locations for simple and carcinomatous cysts, the latter being in most cases of the squamous type. Recurrence following the removal of these tumours is common, but metastases are rare though not unknown. Of the cases reported, one patient died from carcinoma of the breast with liver metastasis, which was present at the time of the removal of the cyst.

271 Treatment of Cutaneous Cancer

W. DUBREUILH (*Journ. de Méd. de Bordeaux*, December 30th, 1930, p. 979) remarks that in the *x*-ray treatment of cancer of the skin it is unnecessary and even harmful to apply deeply penetrating rays, since only the surface need be attacked. It is better to use massive doses in a single application than repeated smaller doses which may render the cancer radio-resistant. Sometimes, although the cancer cells are destroyed, the stroma is unaffected, and a papillomatous condition may ensue; this, however, disappears in the process of cure. When the cancer has extended deeper, radium gives better results than *x* rays. In secondary cancer of the skin neither radium nor *x* rays do much good; the same applies to the melanotic types where the method of choice is diathermy or excision. The author is not in favour of electrolysis of these cases. The clinical examination rather than the histological structure is the best guide as to treatment in individual cases. Epithelioma of the upper lip is a cutaneous cancer, but in the lower lip the cancer is orificial or mucous; cure has sometimes been obtained in the latter by employing *x* rays. As regards epithelioma of the face in general the author has come to the conclusion that cases which do not respond to *x* rays or radium are almost always inoperable. Some cases of epithelioma supervening on lupus have been temporarily cured, but never those developing on the scar of a burn.

272 The Thymus in Exophthalmic Goitre

H. SCHLEUSSING (*Zentralbl. f. Chir.*, January 24th, 1931, p. 201) has examined the post-mortem material in 12 cases of toxic goitre; most of the patients died shortly after an operation, with symptoms of hyperthyroidism. In all the thymus was found to be enlarged, and the enlargement was due to the persistence of definite thymus tissue, though the relative amount of cortex and medulla and the numbers of Hassall's corpuscles varied considerably. In some cases other lymphatic tissues in the body were also affected. Of 6 cases where operation was successfully performed, no thymus was found in 4, and the organ weighed about 1 gram and 30 grams respectively in the other two. The larger thymus contained richly calcified Hassall's corpuscles, but otherwise resembled those found in the post-mortem group. The striking contrast between the fatal cases on the one hand and the successful ones on the

other leads the author to conclude that the thymus may play a part in the production of the more serious symptoms of the disease. He suggests that an attempt might be made to reduce the size of the thymus, if present, before an operation is undertaken.

273 Post-operative Ileus

J. BRENNAN (*New York State Journ. Med.*, January 15th, 1931, p. 77) defines two main types of post-operative ileus, the mechanical and paralytic; the former is due to such conditions as adhesions, tumours, volvulus, and intussusception, while the latter is insidious in onset and often overlooked in its early stages. Both show the same clinical course, with the symptom-complex of pain, tympanites, vomiting, and complete constipation; if left unrelieved by enemas, stomach washings, passing of the duodenal tube, and the administration of sodium chloride, the complication may compel further surgical intervention. High obstruction is rapidly fatal; the occurrence of faecal vomiting must be regarded not so much as a symptom of intestinal obstruction as one of approaching death, being too late for surgical cure. There is a similarity of symptoms between the terminal stages of ileus and death from shock or gas gangrene; the fatal termination is probably due to absorption of nucleo-proteins from the degenerated intestinal lining, together with such factors as dehydration and loss of chlorides and alkalosis. Treatment is largely preventive, and necessitates a thorough knowledge of the patient beforehand, study of the blood chemistry, not too early catharsis, and a return to the normal water balance in the body, with, in certain selected cases, the performance of an ileostomy as part of the original operation. In late cases a jejunostomy relieves the toxicity best, and the intestinal contents are replaced with sodium chloride solution, 5 per cent. intravenously and 3 per cent. in large quantities subcutaneously. Some authorities advocate stripping the entire small intestinal tract over a glass tube to empty it thoroughly. Both in diagnosis and in treatment spinal anaesthesia is of value.

274 Chronic Appendicitis

L. R. CHANDLER (*Journ. of College of Surg. of Australasia*, November, 1930, p. 235) insists that it is impossible to make a proper physical examination for chronic appendicitis without assistance. In every case a complete history should be taken and the physical examination include all relevant pathological tests and an *x*-ray investigation of the gastro-intestinal tract. In this way it is possible to eliminate such conditions as peptic ulcer, cholecystitis, mesenteric lymphadenitis, pelvic inflammation, ureteral and kidney disease, diverticulitis, colitis, amoebiasis, intra-abdominal tuberculosis or early malignant disease, subcostal neuritis, hypothyroidism, cardiac disease, epididymitis, and hernia. When chronic appendicitis originates in an acute attack, removal by means of a conservative muscle-splitting operation is recommended, but a rectus incision permitting abdominal exploration is advised in cases of insidious onset. Chandler claims that as the result of paying special attention to accurate diagnosis 95 per cent. of his patients with chronic appendicitis have been cured by appendicectomy.

275 The Frequency of Adenoids in Adults

C. G. VILLANUEVA (*La Med. Ibera*, January 17th, 1931, p. 73) records five cases of adenoids in adults aged from 24 to 40, three of whom were men and two women. He maintains that adenoids are much more frequent in adult life than the textbooks would lead one to suppose. His cases illustrate the diagnostic value of posterior rhinoscopy, for the performance of which all that is needed in the way of preparation is painting the pharynx with a 1 in 10 solution of cocaine. Villanueva declares that many cases of respiratory insufficiency, catarrhal and suppurative otitis, obstinate pharyngitis, laryngitis, and similar conditions in adults are simply due to the persistence of adenoids which serve as foci of localized infection, and can easily be cured by adenoidectomy.

Therapeutics

276 Intermittent Claudication Relieved by Hot Baths

The treatment of intermittent claudication by inducing hyperpyrexia is suggested by H. G. MEHRTENS and P. S. POUPPIRT (*Journ. Amer. Med. Assoc.*, December 20th, 1930, p. 1910), who immerse their patients in baths the temperature of which is kept at 110° F. With timid patients, or on the occasion of the first bath, the temperature is 5° lower. The bath temperature is maintained until the temperature of the patient reaches a point 1½° below the fever required; the bath heat is then reduced until it corresponds with the mouth temperature of the patient. The routine bath lasts one hour, and it is repeated daily for a fortnight or longer. The milder cases were found to have the better chances of improvement, and when gangrene had started no amelioration was obtained. Such hyperpyrexial baths are considered by the authors to be indicated particularly in early cases of vascular disease with symptoms of intermittent claudication. Arterio-sclerosis may also be benefited thus, especially when there is calcification of the peripheral vessels. Complications are averted by carefully watching the patients, and modifying the treatment according to individual requirements.

277 Treatment of Leprosy

G. H. WILDISH and D. G. STOUTE (*Journ. Med. Assoc. of South Africa*, January 10th, 1931, p. 21) reports successful results in the treatment of leprosy following the alternation of intravenous injections of tartar emetic with the oral administration of potassium iodide. Commencing with 10 grains of potassium iodide three times a day for three or four days, the appearance of reactions led to this treatment being suspended, and intravenous injections of 0.25 grain of tartar emetic twice each week being substituted, the dose being increased gradually according to the degree of its tolerance by the patient. Two courses of the two drugs were usually sufficient to produce a marked improvement in the macules, the edges of which became dry, flattened, and desquamating. The pains and cramps lessened, and the general condition of the patients was obviously better. An interval of a fortnight was allowed between the two courses. The authors mention that the reactions to look for are exacerbations of any of the leprous lesions, leprotic fever, iodide reactions, and sudden impairment of the general physical condition of the patient. No patient complained of any ill effects, and the combined treatment became very popular. Some reacted to very small doses of potassium iodide, even to single doses of 2 grains.

278 Intraperitoneal Administration of Iron

C. G. GRULEE and H. N. SANFORD (*Amer. Journ. Dis. Child.*, January, 1931, p. 53) commend the intraperitoneal injection of iron in doses of 5 mg. at three-day intervals, combined with ultra-violet light irradiation, or with one or two transfusions of blood, for the treatment of children suffering from secondary anaemia. They found that although there was little or no rise in the haemoglobin or red cells during the time of injection, or about 30 days, there ensued subsequently a haemoglobin rise to the extent of 5 per cent. a week. The view is held that secondary anaemia is more particularly due to inability to use the iron taken into the body than to an actual shortage, and that the therapeutic administration of iron in this way creates a reservoir on which the body may draw. The ultra-violet irradiation was supplied, therefore, to assist the assimilation of iron, and in certain cases one or two intraperitoneal injections of citrated blood were given with the same intent. The method adopted was to inject 5 c.cm. of colloidal iron as ferric hydroxide, the solution containing 8 mg. of the metal; this standard amount was used irrespective of the weight of the child. The injections were given twice a week for four weeks, after which the child was sent home from hospital, and monthly blood

estimations were made. Control experiments were associated with the clinical investigation, and it was shown that the combination of iron therapy with blood transfusion or irradiation was essential for success. The ages of the children ranged from 9 months to 2 years, and the beneficial results were permanent. No adverse reactions occurred, except when attempts were made to increase the dosage. No benefit was obtained in cases of primary anaemia.

279 Endocrine Treatment of Gastric and Duodenal Ulcer

S. J. ESSENSON (*Med. Journ and Record*, December 3rd, 1930, p. 549) advocates the use of intramuscular parathyroid injections as the best means of stopping that hypermotility which, with hyperperistalsis, is one of the most prominent signs of gastric or duodenal ulcer. With the cessation of epigastric discomfort, vomiting, haemorrhage, and hyperacidity, surgical intervention is contraindicated, and treatment must aim at overcoming the hypermotility and pylorospasm. While atropine gives temporary relief to the latter, the most reliable remedy is parathyroid administered intramuscularly, accompanied by diet, rest, and neutralization of the hyperacidity. Notes of four cases from his clinic are given in which intramuscular injections of from 20 to 30 units of parathyroid with 1/100 grain of atropine were given daily, or every other day, with marked improvement in all instances.

280 Diathermy in Renal Colic

G. BOISSON (*Paris Méd.*, January 24th, 1931, p. 92) records a personal experience. Following previous attacks of renal colic, he was awakened one night from sleep by the characteristic pain. A hypodermic dose of sédol gave no relief. He tried diathermy, with one electrode on the dorso-lumbar region and a large electrode on the abdomen. The strength of the current was raised gradually to 3,000 milliamperes, and eventually to 4,000 milliamperes. Twelve minutes from the commencement of treatment he experienced marked relief; in half an hour he was bathed in sweat. After an interval of three hours he tried a second period of treatment, following which he passed a tiny calculus of oxalic acid. In previous attacks the spasms of pain had lasted for thirty-six hours, and the calculi passed with great difficulty and suffering. Two months later he had a further attack, and at once tried diathermy again in two similar periods of treatment. Eight hours after the commencement of the crisis he passed a small oxalic acid calculus without the usual violent pain.

Ophthalmology

281 Central Nervous Control of the Ocular Mechanisms

H. A. RILEY (*Arch. of Ophthalmol.*, November, 1930, p. 640), after asserting that there is probably no synergism in the action of the extraocular muscles, and discussing the various pareses, details the causes of interference with the peripheral nervous mechanism as those capable of producing neuritic processes elsewhere (toxic, metabolic, or infectious disorders, aneurysmal, neoplastic, or traumatic), and those operating in the orbit, sinuses, or cranial cavity. He states the positions of the various nuclei in the brain stem—there not being general agreement in the case of the muscular subdivisions of the third cranial nerve—and discusses the possibility of centres for vertical and lateral deviation, convergence, and divergence. The evidence in support of all but the last is, he holds, practically conclusive. In the reflex movements of the eyeball the acoustic and vestibular divisions of the eighth connect with the oculomotor nuclei to move the eyes in obedience to auditory and postural stimuli, as in the production of nystagmus. In the second part of his paper (ibid., December, 1930, p. 885) Riley points out that while cortical and supranuclear lesions involve one or more muscles, and the reflex control of the vestibular apparatus is present, lesions of the nuclei affect only one muscle and vestibular control, and those of a specific centre influence single movements. In pure gaze paralysis there is no diplopia, while in intra-axial involvement there are associated brain-stem lesions. An isolated paralysis of the fourth or sixth nerve usually indicates a root lesion, in the absence of other neurological symptoms. Diseases attacking the nuclei, neuraxial centres, and intra-axial root fibres are: congenital aplasia; chronic progressive external ophthalmoplegia (probably an abiotrophy); intoxication—exogenous (metals, gases, and food), and intoxication—endogenous (nephritis, diabetes, gout, Graves's disease, and metabolic diseases); infections (tuberculosis, syphilis, typhoid, influenza, pneumonia, exanthems, and diphtheria); neoplastic; vascular; and traumatic. Various oculomotor syndromes are then detailed. Cramps and isolated movements mostly attack the third nerve (especially the levator palpebrae superioris, the internal rectus, and the internal muscles). Nystagmus is subdivided into the following types: oscillatory, rhythmic (in irritation), fixation (in disseminated sclerosis), unilateral (breaking of internuclear links), miners', congenital, and symptomatic, found in degenerative states, intoxications, and cerebellar and upper cervical cord disease. The extrapyramidal system controls the ocular movements by the cerebellum, and by the striatal system governed by the basal ganglia. The cerebellum probably does not endue the eye muscles with synergism. This system is attacked by epidemic encephalitis, which causes ocular deviations. Riley traces the phylogeny of cortical control, and describes the centres for voluntary movement and preservation of fixed gaze. Disturbances of cortical control always affect gaze movements (as in convulsive seizures, neoplastic pressure, inflammation, infection, and meningeal thickening); an irritative stage causes gaze deviation, preceding a stage when the gaze is paralysed. The diagnosis of hysteria is best confined to those cases which present symptoms of the higher-centre type only.

282 Pathogenesis of Sympathetic Ophthalmia

T. BARRAQUER Y CERERO (*Arch. de med., cir. y esp.*, November 15th, 1930, p. 449) remarks that numerous discordant views prevail as to the pathogenesis of sympathetic ophthalmia. One view is that the infection passes from the wounded eye to the other by the circulation; others maintain that the route is first the optic nerve of the primarily affected eye, then the optic chiasma, and lastly the optic nerve of the other eye; while according to others the first occurrence is a sympathetic irritation, which then degenerates into ophthalmia and follows the tract formed by the optic and ciliary nerves. The author holds that the last view may be rejected, since Gama Pinto has shown the fundamental difference between sympathetic irritation and ophthalmia, the former being only a disturbance of function, while the latter is an infectious disease with characteristic lesions. The supporters of the other theories declare that they have found infective organisms after death in one or both of the optic nerves or the ciliary nerves, or walls of the ciliary vessels on one or both sides. The present author, however, is inclined to regard these organisms as merely due to contamination, since otherwise they would have given rise to meningitis or septicaemia. He maintains that sympathetic ophthalmia is due to a delayed process of formation of antibodies, which is interrupted by the rapid development of panophthalmia or ocular suppuration.

283 Ocular Manifestations of Trichinosis

L. F. CARTER (*Journ. Amer. Med. Assoc.*, November 8th, 1930, p. 1420), who records three illustrative cases, states that the most spectacular and characteristic ocular symptom of trichinosis is chemosis of the bulbar conjunctiva, which occurs in 50 per cent. of the cases. The chemosis is limited to the conjunctiva overlying the external and internal rectal muscles, gradually fading at the limbus. The chemosis, which often lasts only a week, is usually associated with oedema of the lids; this later extends over the temporal and frontal regions, and finally may involve the entire face. Painful movement of the eyes is frequent. Exophthalmos, conjunctival ecchymosis, mydriasis, and retinal haemorrhages occur with varying degrees of frequency. At post-mortem examinations numerous trichinellae have been found in the ocular muscles.

Obstetrics and Gynaecology

284 Post-partum Haemorrhage

W. S. SMITH (*New York State Journ. Med.*, February 1st, 1931, p. 141) reviews the incidence of post-partum haemorrhage in 9,000 consecutive deliveries during the last ten years, classing under this heading all patients who had more than a moderate loss of blood after labour had terminated. There were 67 post-partum cases in his series, and two patients died, corresponding to an incidence of 0.74 per cent., and a mortality of 0.023 per cent. According to the author the incidence of post-partum haemorrhage in a number of large obstetrical departments ranges between 13 and 0.32 per cent., while the mortality percentage is between 0.28 and 0.007; the average incidence is stated as 3.5 per cent., and the average mortality as 0.09 per cent. He attributes his own low figures to the fact that he employed the Dickinson-Pomeroy technique, which includes (1) the administration of pituitrin as soon as the child has been delivered; (2) prompt expression of the placenta at the time of the first uterine contraction after delivery; (3) the immediate lifting of the uterus out of the pelvis by abdominal manipulation; (4) the occasional use of a second dose of pituitrin and the administration of ergot; and (5) employment at times of the lifting vaginal pack, with or without an abdominal binder. Smith believes that there is no need in post-partum haemorrhage to use the intrauterine pack. He insists that unceasing vigilance in the control of small blood losses at the start is the method by which the obstetrician may lessen the incidence of such haemorrhage, and quotes the aphorism, "The only safe uterus is the empty uterus."

285 Toxaemias of Pregnancy

Discussing the toxaemias of pregnancy, J. R. GOODALL (*Can. Med. Assoc. Journ.*, January, 1931, p. 112) believes that the time-honoured division of these conditions into those of the first and second halves of pregnancy respectively is clinically sound. Toxaemia in the first half of pregnancy has often a considerable neurotic factor, and the relative importance of this in comparison with the actual toxic state has to be defined in most cases if treatment is to be effective. The alimentary canal is always involved, and this calls for the taking of light meals every three to four hours in order to secure that the stomach does not remain empty for long intervals. When vomiting persists, and acidosis ensues, intravenous injections of 500 c.cm. of a 10 per cent. solution of glucose in saline are most valuable. If the improvement is only transitory the injection should be repeated; but the quantity here recommended should not be much exceeded. The oral administration of sodium bicarbonate and the bromides is helpful also. Toxaemias of the second half of pregnancy fall into three classes: (1) cases of chronic nephritis complicated by pregnancy; (2) the pre-eclamptic or true toxaemias of pregnancy; and (3) toxaemias of kidneys of low reserve. Goodall discusses in detail the treatment indicated in each class, and emphasizes the importance of withdrawing 300 to 400 c.cm. of blood in eclamptic convulsions, followed by fine intravenous injection of glucose in saline solution. In this second class it is very important to recognize the condition early, and to begin treatment before any great damage has been done.

286 Diseases of the Placenta

As the result of examining twelve placentas from patients with pregnancy toxaemia and albuminuria, twelve from syphilitic subjects, and nine from normal patients, M. RIVIÈRE (*Gynécol. et Obstét.*, December, 1930, p. 481) concludes that the morbid histological processes which have been reported as characteristic in the first two groups are shared by them in common, and are found with equal frequency (although diminished intensity) in the normal group. The changes comprise syncytial exuberance, capillary angiomata, vascular obliteration, and necroses of the villi. Rivière concludes that at present the histological diagnosis of an "albuminuric" or syphilitic placenta is impossible. The case is cited of a woman whose placenta was examined after two successive pregnancies. The first was accompanied by toxaemia and much albuminuria, and the placenta showed the microscopical characters which have been attributed to the "albuminuric placenta." The placenta of the second pregnancy, which was normal and not associated with albuminuria, proved to be exactly similar. It appears that the normal senescence of the placenta may give rise to histological changes similar to those seen in it in syphilis and albuminuria.

287 Radium Treatment of Carcinoma of Cervix

H. C. PITTS and G. W. WATERMAN (*Amer. Journ. Obstet. and Gynecol.*, November, 1930, p. 607) report a series of 92 cases of carcinoma of cervix, definitely diagnosed by microscopical examination, and treated at the Rhode Island Hospital from 1921 to 1924. The available radium consisted of three 50 mg. tubes with 0.5 mm. silver filters and 1 mm. brass capsule; two 25 mg. tubes filtered in the same manner; and ten 5 mg. steel needles. The capsules were placed in the cervical canal, usually two 50 mg. tubes in tandem, enclosed in a piece of rubber tubing 4 mm. thick. The remaining radium was placed against the cervix, being held in position by iodoform gauze packing. The steel needles were inserted about the periphery of the growth. An exposure of 3,500 to 5,000 milligram hours was given, divided in two to three doses at two to three weeks' intervals. The records show that at the end of the three-year period there were 23.6 per cent. of the traced patients alive and clinically free from disease. At the end of the five-year period 18.2 per cent. of traced patients were alive and well. The percentage of five-year cures in the fifth decade group is quite markedly higher in spite of a lower operability rate than either the preceding or succeeding decade. The authors plead for a uniform method of classifying cases and of reporting results so as to render possible a true comparison of the figures of different clinics.

288 Radiological Diagnosis of Ectopic Gestation

According to F. SZELLÖ (*Zentralbl. f. Gynäk.*, January 24th, 1931, p. 224) *x*-ray diagnosis of extrauterine pregnancy is often possible in cases in which the foetus is retained towards or beyond term, but the radiological detection of extrauterine foetal parts has not been found feasible before the fifth month of pregnancy. He records two cases in which extrauterine (intraligamentary) pregnancies were demonstrated by *x*-ray examinations during the fourth month; in one instance diagnosis had remained uncertain in spite of exploratory puncture of the pouch of Douglas. A negative radiograph during the first half of pregnancy must not be regarded as excluding ectopic gestation. The author remarks that the detection of foetal bones placed symmetrically in the pelvis does not —as has been stated by others—point necessarily to intrauterine gestation; careful correlation of the radiological findings with those of a bimanual clinical examination is necessary.

289 Rupture of the Uterus during Labour

T. M. HEALY (*Journ. Obstet. and Gynaecol. of the British Empire*, Winter, 1930, p. 827), who records five cases of uterine rupture during labour, believes that total hysterectomy is unnecessary in such emergencies if provision is made for free drainage through the cervical canal and vagina, as well as through the abdominal wall. Incomplete ruptures, and complete ruptures discovered after delivery, can usually be adequately treated through the vagina. When a diagnosis of complete rupture is made before delivery, Healy considers that the best results will be obtained by opening the abdomen at once, without any vaginal investigation or manipulation, and without any regard to the extent to which the child has left the uterus. He found that in his cases the breasts apparently functioned quite normally in the absence of the uterus and ovaries; in one instance there was no secretion of milk, but this was apparently due to the debilitated condition of the patient.

Pathology

290 Non-specificity of the Scarlet Fever Streptococcus

T. TOYODA, J. MORIWAKI, Y. FUTAGI, and S. HOSHIZAKI (*Brit. Journ. Child. Dis.*, October–December, 1930, p. 282) applied the following tests to determine the specificity of the haemolytic streptococcus associated with scarlet fever: (1) carbohydrate fermentation of streptococci isolated from different sources; (2) capability of producing Dick toxin; (3) neutralization of different kinds of streptococcus toxins with scarlet fever convalescent serum; (4) skin test with scarlatinal streptococcus toxin after active immunization with non-scarlatinal streptococci toxins; (5) Schultz–Charlton phenomenon tested with different varieties of the haemolytic streptococcus antitoxin; (6) rate of appearance of scarlatiniform rash after intramuscular injections of different kinds of haemolytic streptococcus toxin; (7) Schultz–Charlton phenomenon produced with different kinds of haemolytic streptococcus antitoxin on each scarlatiniform rash caused by intramuscular injection of different kinds of streptococcus toxin; (8) agglutination tests of different haemolytic streptococci with the serums of scarlet fever patients in the early stages and in convalescence; (9) complement-fixation tests of different haemolytic streptococci with the serums of convalescent scarlet fever patients in early and convalescent stages and the serums of healthy negative Dick reactions; and (10) precipitin reactions of different haemolytic streptococci to the serums of scarlet fever patients. The authors conclude that scarlet fever streptococci cannot be regarded morphologically, biologically, or serologically as possessing a specificity distinguishing them from other haemolytic streptococci.

291 The Plasmodium of Pernicious Malaria

E. MARCHIAFAVA (*Amer. Journ. Hyg.*, January, 1931, p. 1) concludes that the three malarial parasites, the *P. malariae* of quartan, the *P. vivax* of tertian, and the *P. praecox* or *falciparum* of aestivo-autumnal fevers, are distinct and easily distinguishable species. Each has two separate life cycles: the asexual or pyrogenic, in the human body; and the sexual, which begins in man and ends in the mosquito. Pernicious symptoms are connected only with *P. falciparum*, which has clearly differentiated characters. At the peak of the paroxysm the predominating asexual form in the peripheral blood is a plasmodium without pigment, first adherent to and then inside the red cell, exhibiting amoeboid movements; when at rest it is discoid in form, and during activity becomes a ring. This stage is followed by that of a very fine black granular pigmentation, usually peripheral. Another characteristic is its effect on the red cells; these become smaller, shrivelled up and wrinkled, and of a dark yellow, brassy colour. A biological characteristic is the site of sporulation; this occurs usually in the capillaries of the internal organs, not in the peripheral blood. The sexual forms range as regards shape from crescents to almost round varieties. The crescents are characteristic, and give the name to the parasite. Malignant malaria is distinguished by the long duration of the febrile access, the characteristic febrile curve, and the symptoms of the attack. It occurs only in the summer and autumn, and only recent infections or early relapses develop into pernicious malaria. Clinical manifestations of the various forms of this condition are distinguished, including the bilious, pneumonic, and central nervous types.

292 Bacteriology of Yellow Fever

J. E. DINGER, SCHÜFFNER, and SNIJDERS (*Zentralbl. f. Bakt.*, January 20th, 1931, p. 304) have endeavoured to confirm Kuczynski's work on the causation of yellow fever by a diphtheroid bacillus called by him *Bacillus hepatodystrophicans*. It is known that the blood of monkeys suffering from yellow fever is highly infective, and that the virus is present in as small a quantity as a millionth of a cubic centimetre. If the virus is of a bacterial nature, it should be possible to cultivate it *in vitro*. Portions of the liver and heart were removed under aseptic conditions from *rhesus* monkeys that had died of typical yellow fever, and cultures were made on Kuczynski's special medium. From 6 out of 11 monkeys an organism was recovered in pure culture which appeared to be identical with *B. hepatodystrophicans*. Some of the negative cultures were inoculated into fresh tubes of the same medium, and it was found that after three to five subcultures the same organism suddenly appeared. Experiments with uninoculated medium suggested that these diphtheroid bacilli were probably derived either from the air or from the rabbit or guinea-pig liver used in the preparation of the medium. Attempts to infect monkeys with the organisms recovered, as well as with Kuczynski's own original cultures, proved completely negative. It was found, moreover, that the yellow fever virus would not remain virulent for even two days in cultures of the diphtheroid bacilli. The authors conclude that these organisms have nothing to do with the causation of yellow fever.

293 Production of Encephalitis with Vaccinia Virus

A. ECKSTEIN (*Zeit. f. Hyg. u. Immunitäts.*, January 15th, 1931, p. 151) injected vaccine lymph, in doses of 0.00078 to 0.1 c.cm., by the suboccipital route into the spinal fluid of monkeys. After three days the monkeys became unduly quiet, and exhibited a certain stiffness in their movements. These symptoms were succeeded by spastic paralyses affecting the front or hind limbs; ocular paralyses were noticed in two animals. Later the animals adopted the semi-recumbent position, and were no longer able to reach for food, though they were able to swallow it if it was placed in their mouths. Respiration became increasingly difficult, and death occurred between the sixth and fifteenth days. Of the 17 animals inoculated, one showed no symptoms, and two others were killed after six and eight weeks respectively. Histological examination of the brain of the fatal cases showed the presence of a meningo-myelo-encephalitis. Two control monkeys were inoculated intraspinally, one with 3 c.cm. of saline and one with 0.1 c.cm. of heated vaccine lymph; both remained perfectly well. Three monkeys injected into the carotid artery with 0.1 to 0.5 c.cm. of fresh lymph developed no symptoms, though fourteen days later they failed to react to the intracutaneous inoculation of vaccinia virus. Three additional monkeys were injected intraspinally with a mixed culture of the contaminating cocci and bacilli present in vaccine lymph; these monkeys likewise remained well. Though the author draws no definite conclusion about the etiology of post-vaccinal encephalitis in man, he considers that, taken in conjunction with the finding of vaccinia virus in the spinal fluid of three cases (Gildemeister, Eckstein, and H. and K. Herzberg), the production in monkeys of a similar meningo-myelo-encephalitis must be regarded as significant.

294 Anaemia and Diet

C. FUNK and A. LEJWA (*Bruxelles-Médical*, January 18th, 1931, p. 331) have submitted young rats to various experimental diets without producing any persistent anaemia in these animals. They were also unable to confirm the observations of other workers that copper has any erythropoietic action. In all the young rats, under 60 grams in weight, there was a marked anaemia, the red cells being lowered even to 2 million per c.mm.; but this diminution was regarded as physiological, and it disappeared when the period of rapid growth had ceased. Yeast or liver, whether administered by the mouth or injected in the form of extracts, has the tendency to diminish the number of the red cells. Funk and Lejwa consider that diets probably contain two substances—one which diminishes the number of the red cells, and a second which has the contrary action. They have endeavoured to separate these two principles from yeast and from liver, and conclude that yeast contains less regenerating substance or more diminishing substance than liver.

The Treatment of Rheumatism, Lumbago, Sciatica, Neuritis, Gout, etc. where due to excess of Uric Acid, by

AGOTAN (Howards)

Weintraud found that in gouty patients on a purine-free diet it **more than doubled the quantity of uric acid excreted in the urine.** Chase and Fine maintain that in normal and gouty individuals it induces an augmented excretion of uric acid in the urine and a decreased concentration in the blood by endowing the renal cells with **an increased power for eliminating uric acid.**

Some Medical Opinions:

M.B., Ch.B.:

"The gouty subject has a notoriously sensitive stomach and an impatient disposition. Many remedies for his condition which we know to be good have to be abandoned for one or other of these two reasons. Agotan, which is a recognised eliminant of uric acid, can be used in such cases in the form of an ointment either alone or assisted by radiant heat. This ointment should be rubbed in *not merely over the area actually* affected in cases of 'rheumatism' or 'gout,' but for several inches all round so as to ensure absorption of a sufficiency of the drug. Both acute and chronic conditions of this kind are markedly benefited by it, and in Neuritis it is a veritable boon to all concerned."

M.B., B.Sc., D.P.H.:

Reports that he has achieved success with Agotan when salicylates, iodides, ionisation and diathermy, etc., have all been, to use his own expression, "utterly futile." "With Agotan," he writes, "one can safely prophesy an ultimate cure. Even in cases where ultimate resort had had to be made to morphine this can be discontinued in a very short time. Progress towards recovery is never interrupted by exacerbations as is so common with the majority of other drugs."

M.D., C.M., D.P.H., etc.:

"I have run through the whole gamut of B.P. remedies, and I have tried, I think, all the proprietary uric acid solvents of the present day, but after many years of experience I have come to rely on AGOTAN as the most trustworthy preparation at present available. The conditions in which it may be prescribed with confidence embrace all forms of subacute rheumatism, muscular rheumatism or myalgia, including sciatica, brachial neuritis and gout, whether acute or chronic, and most of the gouty skin diseases. The last group often yields remarkably well to AGOTAN."

NOTE.—The ointment may be used alone or in conjunction with Howards' Agotan Tablets.

AGOTAN is the all-British make of Phenyl Cinchoninic Acid B.P.C. and is sold as powder in 1-oz. bottles and in 7½ grain tablets in bottles of 25 and 50 tablets, and in ointment form in collapsible tubes.

The field for Diathermy Current applications is rapidly increasing

DIATHERMY

MEDICAL AND SURGICAL

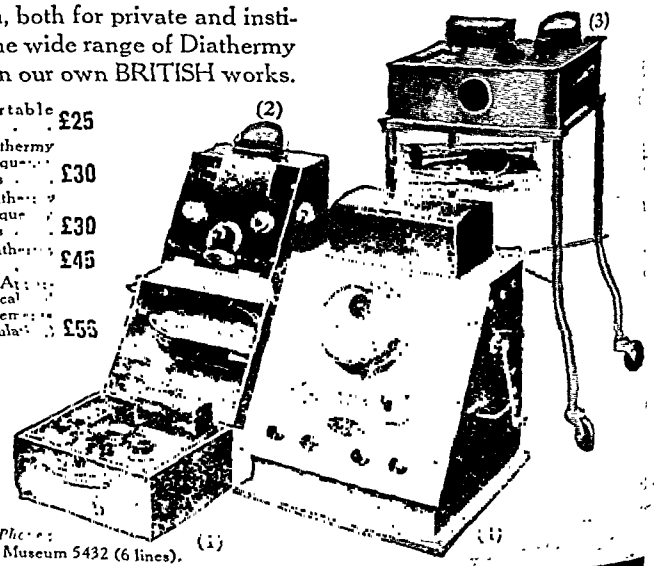
EVERY requirement of the profession, both for private and institutional purposes, is provided for in the wide range of Diathermy Apparatus designed and manufactured in our own BRITISH works.

Machines available:—

FOR SURGERY
e.g.: Surgical cutting by High Frequency indulations or coagulation.

FOR THE PHYSICIAN
for treatment purposes only.
also
FOR BOTH SURGICAL and MEDICAL.

No. 1. "EMESAY" Portable Diathermy . . . £25
No. 2. "AMAZON" Diathermy and High Frequency Current Apparatus . . £30
No. 3. "MERIDIAN" Diathermy and High Frequency Current Apparatus . . £30
No. 4. "EQUATOR" Diathermy Apparatus . . . £45
No. 5. "MEDITHERM" Apparatus for both Medical and Surgical requirements (cutting and coagulation) £55



Please write, 'phone or call to-day for illustrated Diathermy Catalogue No. B37.

GAMAGES 1931 LIVERIES ARE GREATER VALUE THAN EVER

The prices of materials are at their lowest ebb for years. Gamages have been able to make some exceptionally keen purchases of their standard Livery Cloths at the rock bottom of the market. The result is that Gamages well-tailored, high-grade Liveries have in every case been reduced. The trend of the market is upward. Equip your Chauffeur while these exceptionally low prices last.

CHAUFFEURS' BLUE SERGE SUITS

This outstanding example of Gamages Livery Tailoring comprises Double-breasted Jacket, Vest, and Trousers made from a good weight Navy Blue Ribbed Serge. This suit combines neatness with style, and can be purchased Ready for Service. PRICES:

70/- 90/- and £5 10 0

Made to measure if required at same prices.

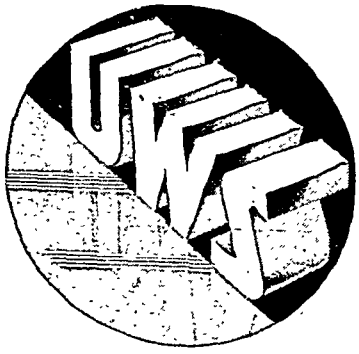
THE MOST SATISFACTORY METHOD OF ENSURING A SOFT WATER SUPPLY



Special Booklet Sent Free on Request "Soft Water in the Home," an illustrated sixty-four page booklet, will gladly be sent to any doctor upon request.

It is a fact of considerable significance that 'Permutit' Water Softening Plants are to-day to be found in over 15,000 homes, and in the leading hospitals, clubs and hotels. No chemicals are used in the 'Permutit' System. This plant provides a soft water which is healthful and palatable to drink, at a moderate initial outlay and an infinitesimal running cost. The plant can be fitted without any alteration to existing arrangements.

THE CROWNING ACHIEVEMENT

U.G.B. MEDICAL BOTTLE *Service*

DURING the past ten years at tremendous expense, a very wide range of automatic machine mould equipment has been built up by the U.G.B. to cater for practically every bottle requirement of the Chemist and Dispenser. New and attractive shapes are now being added from time to time.

The Crowning Achievement was the introduction of the "Washed and Sterilised Ready-to-Use Package" which is daily growing in demand.

Only a small percentage of the actual cost of this service is passed on to the customer.

Supplied either for corks or complete with Rustless White Enamelled Screw Caps.

Once you have experienced the value and convenience of this U.G.B. Service you will use nothing else. Try it NOW and be prepared for the WINTER.

Obtainable from all leading Wholesalers.

Telephones: Langham 1411-1412.
Secretary: N. Rutherford Watson.

FOR DEAFNESS
Doctors prefer "ARDENTE" because—

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sounds from varying ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

FREE HOME TESTS
arranged for Doctors and Patients.
Medical Prescriptions made up to the minutest detail.

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

MEDICAL REPORTS.
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

"VARIBAN"

Elastic Plaster BANDAGE

MADE from a specially woven selvedge material, possessing very elastic properties, evenly spread with an Antiseptic Zinc Oxide Paste. Self-adhesive, readily conforming to the shape of the limb, and when carefully applied forms an even surface dressing which will not crease or slip. Firm support. Easy to remove. Extensively used in many well-known hospitals for the treatment of VARICOSE ULCERS, VARICOSE VEINS, SURGICAL and ORTHOPAEDIC CASES, etc. Their application for treatment of Varicose Ulcers, etc., does not necessitate the patient lying-up; in fact, permits the continuance of light duties. Ensures rapid healing.

STEADY CONTINUOUS WARMTH APPLIED LOCALLY

To Relieve Rheumatic Pains, Chills, etc., and all such Ailments.

The THERMEGA ELECTRIC PAD takes the place of a hot water bottle in all cases where the local application of heat is prescribed. The heat obtained is instantaneous, constant, and easily regulated as desired. The THERMEGA pad, no larger than an ordinary hot water bottle, is handy and practical for use while travelling. It can be used from any lamp-socket or wall plug at any voltage (100-250). The average cost of current is only 1d. an hour (at 6d. a unit). A special Thermostat control maintains a level temperature and makes overheating impossible.

Ask for demonstration and particulars. Sold by all the big stores, chemists, and electrical dealers, or direct from

PRICE: Only 33/-

Famous as **The Food of Royal Infants**

also for invalids, the aged, and all persons of weak digestion

ROBB'S NURSERY BISCUITS have no equal. Easy of assimilation, a nourishing and sustaining diet, its appetising flavour is greatly appreciated by both young and old. Very welcome as a substitute for the ordinary bread-and-milk diet. Can also be lightly baked, with eggs and milk, to supply a delicious custard pudding.

Robb's NURSERY BISCUITS

Highly recommended by eminent Accoucheurs and Physicians throughout the world as the most reliable food for Infants over six or seven months.

ROBB'S NURSERY BISCUIT POWDER is recommended when a feeding bottle is to be used, also as a diet for invalids, Nursing mothers and the aged.

ROBB'S DIGESTIVE RUSKS, TOPS and BOTTOMS, GINGER NUTS, and CHARCOAL BISCUITS are specially recommended for invalids and convalescents.

Send for large free sample and descriptive booklet, etc.

RE-INFORCING THE ABDOMINAL MUSCLES WITHOUT UNDUE PRESSURE!

For those disorders of the abdomen that call for external support, Domen Abdominal Belts have very definite advantages. They give adequate support to the abdomen without setting up pressure to aggravate the patient's condition. And whether it is pregnancy or umbilical hernia, prolapsus uteri, or simply general support, there is a Domen Belt designed specifically for that condition. Domen Belts fit well, sit comfortably and do not get out of place. They leave the patient free and without embarrassment. Full particulars will be forwarded on receipt of your card or a telephoned request.

Advertising Helps the Reader

Readers of the Journal are presented week by week with a comprehensive summary of products necessary to the medical man both in his professional and private life. The advertisement pages of the Journal are carefully scrutinised before going to press, in order that our readers may deal confidently with those firms whose announcements win their interest and attention.

Modern advertising seeks to increase demand, thereby stimulating production and building a circle of prosperity, which ultimately reacts to the advantage of the purchaser himself. Advertised products necessarily maintain a high standard of excellence, for disaster must naturally come speedily to the manufacturer who through any cause and at any time loses the confidence of his customers.

It is the policy of the Journal to convince advertisers that doctors prefer to be approached directly through the pages of their own publication, for in this way we believe manufacturers are encouraged to consider the special needs of the profession, and to state clearly the results of their efforts to meet these requirements when seeking orders from medical men.

The "small" advertisements section provides a *forum* for the "domestic" business of the profession, and those wishing to arrange the Sale or Purchase of Practices, requiring Assistants or Assistancies, and Partners or Partnerships, may in these pages reach thousands of their fellow medical men at very economical cost. Such transactions may, in addition, be protected by the secrecy which the free Box Number service provides.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of **Private Patients** of both sexes of the **Upper and Middle Classes** at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

County Council of Durham.

EARL'S HOUSE SANATORIUM.

MEDICAL OFFICER.

Applications are invited for the post of Medical Officer of Earl's House Sanatorium for Boys, near Durham, which has accommodation for about 80 patients.

The salary will be at the rate of £450 per annum, rising by annual increments of £25 to £500 per annum, together with furnished quarters and board, etc., valued at £150 per annum, in addition. In the case of a married man the emoluments will be paid in cash, as there is accommodation (a cottage) for which a charge of £50 per annum is made by the County Council to cover rent, rates, electric light, and water.

The officer appointed must be a registered Medical Practitioner, and must devote whole time to the duties required of such person by the County Council, including part-time services as an Assistant Tuberculosis Medical Officer. It is essential that the person appointed shall have held House appointments in a General Hospital, and have had practical experience in the administration of a Tuberculosis Sanatorium and in the treatment of tuberculosis in such *an institution*, and in Bacteriological work. Experience in ultra-violet ray treatment and X-ray technique will also be necessary.

The person appointed will be attached to the County Health Department, and will be required, subject to the control of the County Medical Officer of Health, to take full responsibility for the general management of the Institution, including the supervision of the staff and the treatment of patients.

The appointment will be terminable by three months' notice on either side. A deduction of 5 per cent. will be made from the salary in accordance with the provisions of the Local Government and Other Officers Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to the successful candidate passing the County Council's medical examination in connection therewith.

Applications, endorsed "Medical Officer, Earl's House Sanatorium," with copies of not more than three recent testimonials, must be delivered to the County Medical Officer, Shire Hall, Durham, on or before April 4th.

Shire Hall, HAROLD JEVONS,
Durham. Clerk of the County Council.
March 16th, 1931.

Borough of Twickenham.

ASSISTANT MEDICAL OFFICER.

Applications are invited from duly qualified Medical Practitioners (men or women) for the appointment of Assistant Medical Officer. The work will include duties connected with Maternity and Child Welfare, School Medical Inspection and Treatment, and the Borough Hospital for Infectious Disease.

Special experience of Ante-natal and Maternity and Child Welfare work is obligatory, and the possession of a Diploma in Public Health will be an additional recommendation.

Salary £550 per annum, rising by annual increments of £25 to £700.

[illegible] must pass a medical [illegible]ment, and applica[illegible]st to be designated [illegible] and Other Officers Superannuation Act, 1922. The officer will be required to work under the direction and supervision of the Medical Officer of Health; to devote whole time to the service of the Corporation, and to reside within the Borough of Twickenham.

A form of application can be obtained from the Medical Officer of Health, Dr. G. H. DUPONT, Municipal Offices, Twickenham, to whom applications, accompanied by copies of not more than three recent testimonials, are to be sent by April 1st.

Municipal Offices, EDWIN G. STRAY,
Twickenham. Town Clerk.
March 11th, 1931.

St. Peter's Hospital for Stone, ETC.,

Henrietta Street, Covent Garden, W.C.2.

The office of HOUSE SURGEON will fall vacant on April 1st, and applications are invited from male candidates with previous experience in a similar office at a General Hospital. The salary offered is at the rate of £75 per annum, with board, lodging, and laundry.

At the expiration of six months' term of office, and subject to the recommendation of the Medical Committee, the House Surgeon is appointed Resident Surgical Officer for a further similar period. Candidates should therefore be prepared, if successful, to remain at the Hospital for twelve months in all.

Applications, accompanied by copies of testimonials, should be forwarded to the undersigned as early as possible.

BEECHEY ROGERS, Secretary.

Borough of Bacup.

MEDICAL OFFICER OF HEALTH.

[illegible] d for the combined Medical Officer of [illegible]ficer, and Maternity [illegible] Officer.

[illegible] must be fully quali[illegible]es combined in the [illegible]intment will be sub[illegible]e Minister of Health and the Board of Education, and to any terms as to tenure of office or otherwise which they or either of them may impose. The appointment will, in addition, be in all respects subject to the provisions of the Public Health Acts, the Sanitary Officers Order, 1926, and the Local Government (Qualifications of Medical Officers and Health Visitors) Regulations, 1930, so far as the same or any of them are applicable.

The successful applicant will be required to commence his duties at the earliest possible date, and to perform, in addition to the statutory duties or other normal or usual duties of such an appointment, all such other medical, public health, or allied duties as may from time to time reasonably be required of a part-time officer. He will be required to reside at an approved address in or within a reasonable distance of the Borough of Bacup, and, subject to the due performance of his duties as an officer of the Bacup Corporation, will be permitted to engage in private practice.

Office accommodation and stationery will be provided by the Corporation.

The salary, to cover all the duties specified above, will be £400 per annum inclusive.

Further particulars of the appointment may be obtained from the undersigned.

Applications (endorsed "Medical Officer of Health"), stating age, qualifications, Local Government, and/or other experience, and the date when the applicant would be prepared to commence his duties, if appointed, together with copies of three recent testimonials, must reach the undersigned by not later than noon on Saturday, March 28th.

P. J. HODGES, Town Clerk.

Town Clerk's Office,
Stubbylee Hall, Bacup, Lancs.
March 13th, 1931.

Surrey County Council.

COUNTY SANATORIUM, MILFORD, SURREY. (300 Beds.)

Applications are invited from qualified and registered Medical Practitioners for the post of THIRD ASSISTANT RESIDENT MEDICAL OFFICER at this Sanatorium.

Candidates should be under 35 years of age and have held resident Hospital appointments. Sanatorium experience is *not* essential.

The appointment is subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination. The appointment will be made in the first instance for a period of six months, renewable at the end of that period for a further six months. Termination of engagement will be at one month's notice on either side.

The salary is £350 per annum, together with board, lodging, and laundry. These emoluments are valued at £100 per annum for purposes of superannuation.

The successful candidate will be required to devote his whole time to the services of the County Council.

Forms of [illegible] y be obtained from [illegible] of Health, County [illegible] to whom completed [illegible] returned, together [illegible] t testimonials, not [illegible] 4th.

DUDLEY AUKLAND,
Clerk to the Surrey
March 11th, 1931. County Council.

County Borough of Preston.

SHAROE GREEN HOSPITAL, FULWOOD.

Applications are invited for the post of JUNIOR RESIDENT MEDICAL OFFICER. Candidates must be duly qualified and registered under the Medical Acts. Duties include work in any wards of the Hospital as required, and also in the Sharoe Green Maternity Home adjoining.

The appointment is for a temporary period of twelve months only. Salary at the rate of £156 per annum, with board, lodging, etc.

Applications, endorsed "Junior Medical Officer," accompanied by copies of three recent testimonials, to be sent to the Public Assistance Officer, 138, Lancaster Road, Preston, not later than the first post on Friday March 27th.

Town Hall, ALFRED HOWARTH,
Preston Town Clerk.
March 16th, 1931.

City of Cardiff.

CITY LODGE INSTITUTION.

SECOND AND THIRD ASSISTANT MEDICAL OFFICERS.

Applications for the above appointments are invited from duly qualified unmarried Medical Men or Women, who must devote their whole time to the duties, reside in the Institution, and (subject to the Public Assistance Order, 1930, and the Orders of the Council) act under the direction of the Medical Officer of the Institution.

The salary of the Second Assistant will be at the rate of £490 per annum, rising by yearly increments of £25 to £590 a year. The person appointed, if not a transferred officer paying Superannuation contributions under the Poor Law Officers Superannuation Act, 1896, will be required to contribute 5 per cent. of his or her salary under the Superannuation Scheme of the Council, and for this purpose to pass a medical examination, and will be provided with board, lodging, attendance, and washing, for which he or she will pay the sum of £140 a year.

The position of Third Assistant will be tenable for one year only, and the salary will be at the rate of £150 per annum, with board, lodging, attendance, and washing.

Assistant Medical Officers are liable to be called upon by Justices to examine and certify persons alleged to be of unsound mind. Any fees payable in respect of such examinations [illegible] recommendations under [illegible] ct, 1930, and any fees [illegible] must be returned to the Council.

Applications on forms to be obtained from the Public Assistance Officer, 11, Park Place, Cardiff, from whom further information may be obtained, must reach me by 5 p.m. on Wednesday, April 8th.

Direct and indirect canvassing is prohibited.

CECIL G. BROWN,
Town Clerk.

Administrative County of Essex.

JUNIOR ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

The County Council of the Administrative County of Essex invite applications for the above post from registered Medical Practitioners holding a Diploma of Public Health, and not over 45 years of age.

Preference will be given to candidates who have had at least three years' experience in Public Health work subsequent to their medical qualification. The salary attached to the appointment will be £500 per annum, and will rise by annual increments of £25 to £700 per annum. Travelling expenses will be paid by the Council.

The person appointed will be required to devote his whole time to the service of the Council, and to perform such duties and to furnish such advice and assistance appertaining to his office as may be required, and to reside in such district of the County as the Council may decide. The appointment will be subject to three months' notice on either side.

The person appointed will be required to pass a medical examination, and to contribute 5 per cent. of his salary to the fund established under the Local Government and Other Officers [illegible] cribed form, obtained [illegible] nd accompanied by [illegible] three testimonials, which will not be returned, should be addressed to me and delivered at the Shire Hall, Chelmsford, not later than 10 a.m. on Monday, April 6th.

Shire Hall, JOHN H. GOOLD,
Chelmsford. Clerk of the County Council.

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.
